## ABSTRACT

A measurement of the cross section of top quark pair production in proton–proton collisions recorded with the ATLAS detector at the Large Hadron Collider at a centre-of-mass energy of 7 TeV is reported. The data sample used corresponds to an integrated luminosity of  $2.05 \text{ fb}^{-1}$ . Events with an isolated electron or muon and a  $\tau$  lepton decaying hadronically are used. In addition, a large missing transverse momentum and two or more energetic jets are required. At least one of the jets must be identified as originating from a  $b$  quark. The measured cross section,  $\sigma_{t\bar{t}} = 186 \pm 13 \text{ (stat.)} \pm 20 \text{ (syst.)} \pm 7 \text{ (lumi.) pb}$ , is in good agreement with the Standard Model prediction.

## 1. Introduction

Measuring the top quark pair ( $t\bar{t}$ ) production cross section ( $\sigma_{t\bar{t}}$ ) in different decay channels is of interest because it can indicate physics beyond the Standard Model (SM). In the SM, the top quark decays with a branching ratio close to 100% into a  $W$  boson and a  $b$  quark, and  $t\bar{t}$  pairs are identified by either the hadronic or leptonic decays of the  $W$  bosons and the presence of additional jets. The ATLAS Collaboration has previously used the single-lepton channel [1] from a  $35 \text{ pb}^{-1}$  data sample, and the dilepton channels including only electrons and muons [2] from a  $0.7 \text{ fb}^{-1}$  data sample, to perform cross-section measurements at 7 TeV proton–proton centre-of-mass energy. Similar measurements have been performed by the CMS Collaboration [3–5]. All these measurements are systematics limited.

The large data samples for  $t\bar{t}$  production at the Large Hadron Collider (LHC) provide an opportunity to measure  $\sigma_{t\bar{t}}$  using final states with an electron or a muon and a  $\tau$  lepton with high precision. The  $\sigma_{t\bar{t}}$  in this channel has been measured at the Tevatron in  $p\bar{p}$  collisions at 1.96 TeV with 25% precision [6] and recently by the CMS Collaboration at the LHC with 18% precision [7]. A deviation from the value of  $\sigma_{t\bar{t}}$  measured in other final states would be an indication of non-Standard Model decays of the top quark, such as a decay to a charged Higgs ( $H^+$ ) and a  $b$  quark with  $H^+$  decaying to a  $\tau$  lepton and a  $\tau$  neutrino, or of contributions from other non-Standard Model processes [8–10]. Upper limits on the

branching ratio of top quark decays to  $H^+$  bosons decaying to a  $\tau$  lepton and a neutrino have been published by Tevatron and LHC experiments [11–13].

## 2. Analysis overview

This analysis uses  $2.05 \text{ fb}^{-1}$  of data collected by ATLAS from  $pp$  collisions in the LHC at a centre-of-mass energy of 7 TeV between March and August 2011. The  $t\bar{t}$  events are selected with kinematic criteria that make use of the fact that they feature two  $W$  bosons and two  $b$  quarks. The selections favour events with one  $W$  decay to a charged  $\ell$  (with  $\ell$  denoting an electron or a muon; either prompt or from a  $\tau$  lepton decay to  $\ell$ ) and a neutrino and the other  $W$  decays to a  $\tau$  lepton and a neutrino with the  $\tau$  lepton in turn decaying hadronically. In addition at least one jet is tagged ( $b$ -tag) as originating from a  $b$  quark ( $b$ -jet) by means of an algorithm that can identify  $b$ -jets with high efficiency while maintaining a high rejection of light-quark jets. Isolated electrons and muons are well identified, but because of the large cross section for multi-jet production the background from jets misidentified as isolated electrons or muons is not negligible. This background is reduced by requiring significant missing transverse momentum signalling the presence of energetic neutrinos. Hadronic  $\tau$  lepton decays are more difficult to identify and require elaborate techniques to reject jets and electrons misidentified as a  $\tau$  lepton.

Section 5 describes how the objects used in the event selection are defined. After all selections given in Section 5.2, the dominant background to the  $t\bar{t} \rightarrow \ell + \tau + X$  channel is the  $t\bar{t} \rightarrow \ell + \tau + X$  channel in which the  $\tau$  candidate is from jets misidentified as hadronic  $\tau$  lepton decays. Therefore,  $\tau$  lepton identification ( $\tau$  ID) is critical

\* E-mail address: [atlas.publications@cern.ch](mailto:atlas.publications@cern.ch).

for separating signal and background. The  $\tau$  ID methodology employed in this analysis exploits a multivariate technique to build a discriminant [14]. A boosted decision tree (BDT) algorithm is used [15,16]. The number of  $\tau$  leptons in the selected samples is extracted by fitting the distributions of BDT outputs to background and signal templates. Section 6 describes how the background templates are constructed using control data samples. They exploit the fact that events with  $\ell$  and  $\tau$  candidates of opposite sign charge (OS) contain real  $\tau$  leptons while those with same sign charge (SS) are pure background. Events with  $\tau$  leptons are not all from  $t\bar{t}$ ; the contribution from processes other than  $t\bar{t} \rightarrow \ell + \tau + X$  is estimated from Monte Carlo simulation. Section 7 describes the fitting procedure and the results of the fit. The fit results are also checked using an alternative method, referred to as the “matrix method”, based on a cut on the BDT output (Section 7.1). The measured cross section is given in Section 8 and the conclusions are in Section 9.

### 3. ATLAS detector

The ATLAS detector [17] at the LHC covers nearly the entire solid angle around the collision point.<sup>1</sup> It consists of an inner tracking detector surrounded by a thin superconducting solenoid, electromagnetic (EM) and hadronic calorimeters, and an external muon spectrometer incorporating three large superconducting toroid magnet assemblies. The inner tracking detector provides tracking information in a pseudorapidity range  $|\eta| < 2.5$ . The liquid-argon (LAr) EM sampling calorimeters cover a range of  $|\eta| < 3.2$  with fine granularity. An iron-scintillator tile calorimeter provides hadronic energy measurements in the central rapidity range ( $|\eta| < 1.7$ ). The endcap and forward regions are instrumented with LAr calorimeters for both EM and hadronic energy measurements covering  $|\eta| < 4.9$ . The muon spectrometer provides precise tracking information in a range of  $|\eta| < 2.7$ .

ATLAS uses a three-level trigger system to select events. The level-1 trigger is implemented in hardware using a subset of detector information to reduce the event rate to below 75 kHz. This is followed by two software-based trigger levels, level-2 and the event filter, which together reduce the event rate to about 300 Hz recorded for analysis.

### 4. Simulated event samples

Monte Carlo (MC) simulation samples are used to optimise selection procedures, to calculate the signal acceptance and to evaluate the background contributions from single top quark,  $WW$ ,  $WZ$  and  $ZZ$  production and  $Z \rightarrow \tau^+\tau^-$  decays. After event generation, all samples are processed with the GEANT4 [18] simulation of the ATLAS detector, the trigger simulation and are then subject to the same reconstruction algorithms as the data [19].

For the  $t\bar{t}$  and single top quark final states, the next-to-leading-order (NLO) generator MC@NLO [20–22] is used with a top quark mass of 172.5 GeV and with the NLO parton distribution function (PDF) set CTEQ6.6 [23]. The MC@NLO program uses HERWIG [24] to simulate the parton shower and hadronise the partons. The “diagram removal scheme” is used to remove overlaps between the single top quark and the  $t\bar{t}$  final states. The  $t\bar{t}$  cross section is normalised to the prediction of HATHOR ( $164^{+11}_{-16}$  pb) [25], which employs an approximate next-to-next-to-leading-order (NNLO) per-

turbative Quantum Chromodynamics (QCD) calculation. The diboson samples are generated with HERWIG.  $W + \text{jets}$  events and  $Z/\gamma^* + \text{jets}$  events (with dilepton invariant mass  $m_{\ell^+\ell^-} > 40$  GeV) are generated by the ALPGEN generator [26] with up to five outgoing partons from the hard scattering process, in addition to the lepton pairs.<sup>2</sup> The MLM matching scheme [27] of the ALPGEN generator is used to remove overlaps between matrix-element and parton-shower products. Parton evolution and hadronisation is handled by HERWIG, as is the generation of diboson events. The leading-order PDF set CTEQ6L is used for all backgrounds described above.

All samples that use HERWIG for parton shower evolution and hadronisation rely on JIMMY [28] for the underlying event model. The  $\tau$ -lepton decays are handled by TAUOLA [29]. The effect of multiple  $pp$  interactions per bunch crossing (“pile-up”) is modelled by overlaying simulated minimum bias events over the original hard-scattering event [30]. MC events are then reweighted so that the distribution of interactions per crossing in the MC simulation matches that observed in data. The average number of pile-up interactions in the sample is 6.3.

### 5. Object identification and event selection

The event selection uses nearly the same object definition as in the  $t\bar{t}$  cross-section measurement in the dilepton channel [2] with the exception of a  $\tau$  candidate instead of a second electron or muon candidate. The electrons must be isolated and have  $E_T > 25$  GeV and  $|\eta_{\text{cluster}}| < 2.47$ , excluding the barrel-endcap transition region ( $1.37 < |\eta_{\text{cluster}}| < 1.52$ ), where  $E_T$  is the transverse energy and  $\eta_{\text{cluster}}$  is the pseudorapidity of the calorimeter energy cluster associated with the candidate. The electron is defined as isolated if the  $E_T$  deposited in the calorimeter and not associated with the electron in a cone in  $\eta$ - $\phi$  space of radius  $\Delta R = 0.2$  is less than 4 GeV. The muons must also be isolated and have transverse momentum  $p_T > 20$  GeV and  $|\eta| < 2.5$ . For isolated muons, both the corresponding  $E_T$  and the analogous track isolation transverse momentum must be less than 4 GeV in a cone of  $\Delta R = 0.3$ . The track isolation  $p_T$  is calculated from the sum of the track transverse momenta for tracks with  $p_T > 1$  GeV around the muon. Jets are reconstructed with the anti- $k_t$  algorithm [31] with a radius parameter  $R = 0.4$ , starting from energy deposits (clusters) in the calorimeter reconstructed using the scale established using  $Z \rightarrow e^+e^-$  events for electromagnetic objects. These jets are then calibrated to the hadronic energy scale using  $p_T$ - and  $\eta$ -dependent correction factors obtained from simulation [32]. The jet candidates are required to have  $p_T > 25$  GeV and  $|\eta| < 2.5$ . A jet is tagged as a  $b$ -jet by a vertex tagging algorithm that constructs a likelihood ratio of  $b$ - and light-quark jet hypothesis using the following discriminating variables: the signed impact parameter significance of well measured tracks associated with a given jet, the decay length significance associated with a reconstructed secondary vertex, the invariant mass of all tracks associated to the secondary vertex, the ratio of the sum of the energies of the tracks associated with the secondary vertex to the sum of the energies of all tracks in the jet assuming a pion hypothesis, and the number of two-track vertices that can be formed at the secondary vertex. The cut on the combined likelihood ratio has been chosen to give an average efficiency of 70% for  $b$ -quark jets from  $t\bar{t}$  events and a 1% efficiency for light-quark and gluon jets [33].

<sup>1</sup> Atlas uses a right-handed coordinate system with its origin at the nominal interaction point in the centre of the detector and the  $z$ -axis along the beam pipe. The  $x$ -axis points to the centre of the LHC ring, and the  $y$ -axis points upwards. The azimuthal angle  $\phi$  is measured around the beam axis and the polar angle  $\theta$  is the angle from the beam axis. The pseudorapidity is defined as  $\eta = -\ln[\tan(\theta/2)]$ . The distance  $\Delta R$  in  $\eta$ - $\phi$  space is defined as  $\Delta R = \sqrt{(\Delta\phi)^2 + (\Delta\eta)^2}$ .

<sup>2</sup> The fraction of events with  $m_{\ell^+\ell^-} < 40$  GeV is estimated to be less than 0.2% of the total after all selections. The estimate is based on ALPGEN samples for Drell-Yan simulation and confirmed by a good agreement with data.

The missing transverse momentum is constructed from the vector sum of all calorimeter cells with  $|\eta| < 4.5$ , projected onto the transverse plane. Its magnitude is denoted  $E_T^{\text{miss}}$ . The hadronic energy scale is used for the energies of cells associated with jets;  $\tau$  candidates are treated as jets. Contributions from cells associated with electrons employ the electromagnetic energy calibration. Contributions from the  $p_T$  of muon tracks are included, removing the contributions of any calorimeter cells associated with the muon.

### 5.1. $\tau$ reconstruction and identification

The reconstruction and identification of hadronically decaying  $\tau$  leptons proceed as follows:

1. the  $\tau$  candidate reconstruction starts by considering each jet as a  $\tau$  candidate;
2. energy clusters in the calorimeter associated with the  $\tau$  candidate are used to calculate kinematic quantities (such as  $E_T$ ) and the associated tracks are found;
3. identification variables are calculated from the tracking and calorimeter information;
4. these variables are combined into multivariate discriminants and the outputs of the discriminants are used to separate jets and electrons misidentified as  $\tau$  leptons decaying hadronically from  $\tau$  leptons.

Details, including the variable definitions used in the multivariate discriminants, are given in Ref. [9]. In this analysis the outputs of BDT discriminants are used.

Reconstructed  $\tau$  candidates are required to have  $20 \text{ GeV} < E_T < 100 \text{ GeV}$ . They must also have  $|\eta| < 2.3$ , and one, two or three associated tracks. A track is associated with the  $\tau$  candidate if it has  $p_T > 1 \text{ GeV}$  and is inside a cone of  $\Delta R < 0.4$  around the jet axis. The associated track with highest  $p_T$  must have  $p_T > 4 \text{ GeV}$ . The charge is given by the sum of the charges of the associated tracks, and is required to be non-zero. The probability of misidentifying the  $\tau$  lepton charge sign is about 1%. The charge misidentification rate for muons and electrons is negligible.

If the  $\tau$  candidate overlaps with a muon (with  $p_T > 4 \text{ GeV}$  and without an isolation requirement) or an electron candidate within  $\Delta R(\ell, \tau) < 0.4$ , the  $\tau$  candidate is removed. To remove electrons misidentified as  $\tau$  leptons, an additional criterion is used that relies on a BDT trained to separate  $\tau$  leptons and electrons (BDT<sub>e</sub>) using seven variables shown to be well modelled by comparing  $Z \rightarrow e^+e^-$  and  $Z \rightarrow \tau^+\tau^-$  events in data and in MC simulation. The variables were chosen after ranking a large set by their effectiveness.<sup>3</sup> The most effective variables for BDT<sub>e</sub> are  $E/p$ , the EM fraction (the ratio of the  $\tau$  candidate energy measured in the EM calorimeter to the total  $\tau$  candidate energy measured in the calorimeter), and the cluster-based shower width. The BDT output tends to be near 1 (0) if the  $\tau$  candidate is a  $\tau$  lepton (electron). BDT<sub>e</sub> was trained using  $Z \rightarrow e^+e^-$  and  $Z \rightarrow \tau^+\tau^-$  Monte Carlo samples. The  $\tau$  candidate is required to satisfy BDT<sub>e</sub> > 0.51; 85% of reconstructed  $\tau$  leptons decaying hadronically satisfy this requirement, as measured in  $Z \rightarrow \tau^+\tau^-$  events. The additional rejection for electrons is a factor of 60.

The majority of objects reconstructed as  $\tau$  candidates in a multi-jet environment are jets misidentified as  $\tau$  leptons. A jet or an electron misidentified as a  $\tau$  lepton will be referred to as

a fake  $\tau$ . Another BDT (BDT<sub>j</sub>) based on eight variables is used to separate  $\tau$  leptons in  $\tau$  candidates with one track (denoted  $\tau_1$ ) from such jets. For candidates with more than one track (denoted  $\tau_3$ ) BDT<sub>j</sub> includes ten variables. The BDT<sub>j</sub> was trained using multi-jet events as background and  $Z \rightarrow \tau^+\tau^-$  Monte Carlo as signal. The most effective variables for BDT<sub>j</sub> are calorimeter and track isolation, cluster-based jet mass, and the fraction of energy within  $\Delta R = 0.1$  of the jet axis. The BDT<sub>j</sub> distributions are fit with templates for background and signal to extract the number of  $\tau$  leptons in the sample. Details are given in Section 7. The fake  $\tau$  background in the  $\tau_3$  sample is significantly higher than in the  $\tau_1$  sample, leading to very different BDT<sub>j</sub> distributions. Hence independent measurements are carried out for  $\tau_1$  and  $\tau_3$  candidate events and the results are combined at the end. If there is a  $\tau_1$  and a  $\tau_3$  candidate in the event, the  $\tau_1$  candidate is kept as the probability that the  $\tau_1$  is a  $\tau$  lepton is much higher. If there are two  $\tau_1$  or  $\tau_3$  candidates, both are kept.

### 5.2. Event selection

For this analysis, events are selected using a single-muon trigger with a  $p_T$  threshold of 18 GeV or a single-electron trigger with a  $p_T$  threshold of 20 GeV, rising to 22 GeV during periods of high instantaneous luminosity. The offline requirements are based on data quality criteria and optimised using Monte Carlo simulation:

- a primary vertex with at least five tracks, each with  $p_T > 400 \text{ MeV}$ , associated with it;
- one and only one isolated high- $p_T$  muon and no identified electrons for the  $\mu + \tau$  channel, or one and only one isolated electron and no isolated muons for the  $e + \tau$  channel;
- at least one  $\tau$  candidate (as defined in Section 5.1);
- at least two jets not overlapping with a  $\tau$  candidate, i.e.  $\Delta R(\tau, \text{jet}) > 0.4$ ;
- $E_T^{\text{miss}} > 30 \text{ GeV}$  to reduce the multi-jet background, and the scalar sum of the  $p_T$  of the leptons (including  $\tau$ ), jets, and  $E_T^{\text{miss}}$  must be greater than 200 GeV, to reduce the  $W + \text{jets}$  background.

The  $\ell + \tau$  samples are divided into events with no jets identified as a  $b$ -quark jet (0  $b$ -tag control sample) and those with at least one such jet ( $\geq 1 b$ -tag  $t\bar{t}$  sample). The 0  $b$ -tag sample is used to estimate the background in the  $\geq 1 b$ -tag  $t\bar{t}$  sample. Each sample is split into two, one with the  $\tau$  candidate and  $\ell$  having the opposite sign charge (OS), and the other one with  $\tau$  and  $\ell$  having the same sign charge (SS). While the  $\tau$  candidates in the SS samples are almost all fake  $\tau$  leptons, the OS samples have a mixture of  $\tau$  leptons and fake  $\tau$  leptons. The numbers of observed and expected events in the above samples are shown in Table 1. The  $\ell + \text{jets}$  entry is the contribution from all processes with a  $\ell$  and a  $\tau$  candidate that is a jet misidentified as a  $\tau$  lepton other than from  $t\bar{t}$  ( $\rightarrow \ell + \text{jets}$ ). The  $\tau$  entries require the reconstructed  $\tau$  candidate be matched to a generated  $\tau$  lepton. The matching criterion is  $\Delta R < 0.1$  between the  $\tau$  candidate and the observable component of the generated  $\tau$  lepton.

To estimate the multi-jet background from data, an event selection identical to the  $\mu + \tau$  ( $e + \tau$ ) event selection except for an inverted muon (electron) isolation cut is used to obtain a multi-jet template for the shape of the transverse mass,  $m_T = \sqrt{(E_T^\ell + E_T^{\text{miss}})^2 - (p_x^\ell + E_x^{\text{miss}})^2 - (p_y^\ell + E_y^{\text{miss}})^2}$ . The normalisation of each selected data sample is obtained by fitting the  $m_T$  distribution of the selected data samples with the multi-jet template and the sum of non-multi-jet processes predicted by MC, allowing the amount of both to float. The uncertainty on the multi-jet

<sup>3</sup> The effectiveness is quantified by quadratically summing over the change in the purity between the mother and daughter leaves for every node in which the given variable is used in a decision tree.

**Table 1**

Number of  $\ell + \tau$  candidates for Monte Carlo samples and data.  $t\bar{t}(\ell + e)$  are  $t\bar{t}$  events with one identified lepton and an electron reconstructed as a  $\tau$  candidate.  $t\bar{t}(\ell + \text{jets})$  are  $t\bar{t}$  events with one identified lepton and a jet reconstructed as a  $\tau$  candidate.  $\ell + \text{jets}$  are events with one identified lepton and a jet reconstructed as a  $\tau$  candidate from sources other than  $t\bar{t}(\ell + \text{jets})$  and multi-jets. Sources contributing to jet fakes are  $W + \text{jets}$ ,  $Z + \text{jets}$ , single top quark, diboson events and  $t\bar{t}$ .  $Wt(\ell + \tau)$  is  $W + t$  production with one  $W$  decaying to  $\ell$  and another to  $\tau$ . The uncertainties are statistical only, except for the multi-jet estimates. MC samples are normalised to the data integrated luminosity.

background is estimated to be 30%. This estimate is only used to illustrate the background composition. The background models are derived from data (see Section 6) and do not depend on knowing the exact composition. All processes contribute more events to OS than SS because of the correlation between a leading-quark charge and the lepton charge, except for the multi-jet channel contribution which within uncertainties has equal numbers of OS and SS events. As one can see from Table 1, the  $\tau$  leptons are almost all in the OS sample and come mainly from two sources:  $Z \rightarrow \tau^+\tau^-$ , which is the dominant source in the sample with 0 b-tag, and  $t\bar{t} \rightarrow \ell + \tau + X$  which is the dominant source in the sample  $\geq 1$  b-tag. The sources of fake  $\tau$  leptons are quite distinct between the 0 b-tag and the  $\geq 1$  b-tag samples: the first is mainly  $W/Z + \text{jets}$  with small contributions from other channels, the second is mainly  $t\bar{t}$ .

## 6. Background models

The jet origin can strongly influence the  $\tau$ -lepton fake probability. Due to their narrow shower width and lower track multiplicity, light-quark jets have a higher probability of faking a  $\tau$  lepton than other jet types. Thus the  $BDT_j$  distributions have a strong dependence on the jet type. It is therefore crucial to build a background model which properly reflects the jet composition in order to correctly estimate the fake  $\tau$  contamination in the signal region. Deriving this background model from control regions in data rather than MC simulation is preferable in order to avoid systematic effects related to jet composition in the MC models.

The gluon component of the fake  $\tau$  leptons is charge symmetric; therefore it is expected to have the same shape in SS events as in OS events and should contribute the same number of fake  $\tau$  leptons in each sample. The contribution of fake  $\tau$  leptons from gluons can be removed by subtracting the distribution of any quantity for SS events from the corresponding distribution for OS events.

The multi-jet background also cancels, as can be seen in Table 1. The resulting distributions are labelled OS-SS. Similarly, since each sample is expected to have an almost equal contribution from  $b$ -jets and  $\bar{b}$ -jets, the small  $b$ -jet component should also be removed by OS-SS (the asymmetry in  $b$  production, mainly from single top quark final states, is negligible). The only jet types remaining in the OS-SS distributions are light-quark jets. MC studies indicate that the  $BDT_j$  distributions of  $c$ -quark jets misidentified as  $\tau$  leptons are not noticeably different from those of light-quark jets.

One can construct a background  $BDT_j$  distribution from the 0 b-tag data sample by subtracting the expected amount of  $\tau$ -lepton signal. The signal is mainly from  $Z \rightarrow \tau^+\tau^-$  and can be reliably predicted from MC. A control sample dominated by  $W + \text{jets}$  events is considered as a check. The latter sample is selected by requiring events with a muon and a  $\tau$  candidate, no additional jets,  $E_T^{\text{miss}} > 30$  GeV and  $40$  GeV  $< m_T < 100$  GeV. According to MC simulation, in  $W + \text{jets}$  events where exactly one jet is required, 90% of the fake  $\tau$  leptons are from light-quark jets and 10% from gluons. This sample is labelled  $W + 1$  jet.

The  $BDT_j$  background shapes for the OS-SS 0 b-tag and  $\geq 1$  b-tag data samples are not identical to the  $W + 1$  jet distributions for two reasons: (1) the shape depends on the jet multiplicity, (2) different OS/SS ratios are observed in the samples. The dependence on the OS/SS ratio comes from the differences in jet fragmentation producing a leading particle with the opposite charge and the same charge as the initial quark; thus the OS  $BDT_j$  shape from light-quark jets differs from the equivalent SS  $BDT_j$  shape. The ratio of OS-SS  $BDT_j$  background distributions derived from  $W + 1$  jet and  $\geq 1$  b-tag simulated events show that significant corrections are needed (30% for  $BDT_j > 0.8$ , a region dominated by the true  $\tau$  signal). For the 0 b-tag sample the corresponding corrections are much smaller (5% in the same region). Both the 0 b-tag and the  $W + 1$  jet data samples are used to obtain statistically independent estimates of the background in the  $\geq 1$  b-tag sample.

**Fig. 1.** BDT<sub>j</sub> (OS-SS) distributions of  $\ell + \tau$  ( $e$  and  $\mu$  combined) events in the 0  $b$ -tag data (black points): (a)  $\tau_1$ , (b)  $\tau_3$ . The expected contributions from  $\tau$  and  $e$  (sum of  $Z \rightarrow \tau^+\tau^-$ , single top and  $t\bar{t} \rightarrow \ell + \tau + X$ ) are shown as a solid red line. The derived background templates after applying MC corrections are shown as dashed histogram with shaded/blue statistical uncertainty bands. The shapes of these background templates are used for the fits to the  $\geq 1$   $b$ -tag distributions.

Two different approaches are used for constructing backgrounds in the  $\geq 1$   $b$ -tag data sample. One, used by the fit method (Section 7), is to reweight the BDT<sub>j</sub> distribution of the background bin-by-bin using the MC-based ratio of the  $\geq 1$   $b$ -tag background to the background model. In this case the 0  $b$ -tag sample is preferred as it requires smaller corrections derived from MC simulation; the  $W + 1$  jet is used as a cross check. The other approach is to split the background into bins of some variable within which the shapes of BDT<sub>j</sub> distributions of the background model are close to those from the  $\geq 1$   $b$ -tag background. This approach, used in the matrix method cross check (Section 7.1), avoids using MC corrections, but assumes the data and MC simulation behave similarly as function of the binning variable.

## 7. Fits to BDT<sub>j</sub> distributions

The contribution from  $t\bar{t} \rightarrow \ell + \tau + X$  signal is derived from the  $\geq 1$   $b$ -tag data sample by a  $\chi^2$  fit to the OS-SS BDT<sub>j</sub> distribution with a background template and a signal template. The parameters of the fit are the amount of background and the amount of signal. The shapes of the templates are fixed.

Two statistically independent background templates corrected by MC, as discussed in Section 6, are used: one derived from 0  $b$ -tag data, the other (purely as a check) derived from the  $W + 1$  jet data sample. The signal BDT<sub>j</sub> templates for 0  $b$ -tag and  $\geq 1$   $b$ -tag are derived from  $\tau$  leptons in  $t\bar{t}$  and  $Z \rightarrow \tau^+\tau^-$  MC simulation. Contributions to the BDT<sub>j</sub> distributions from electrons passing the BDT<sub>e</sub> cut cannot be distinguished from  $\tau$  leptons so they are treated as part of the signal.

**Fig. 2.** BDT<sub>j</sub> (OS-SS) distributions of  $\ell + \tau$  in the  $\geq 1$   $b$ -tag sample; (a)  $\tau_1$ , (b)  $\tau_3$ . The normalisation of each template is derived from a fit to the data. The fitted contributions are shown as the light/red (signal), dashed/blue (background derived from 0  $b$ -tag after applying MC corrections) and dark/black (total) lines. Shaded/blue bands are the statistical uncertainty of the background template.

The uncertainty on the background templates is determined by the numbers of data and MC simulated events. The signal template for the 0  $b$ -tag control sample has a non-negligible statistical uncertainty (2% for  $\tau_1$ , 5% for  $\tau_3$ ) because of the low acceptance.

The fitting procedure was tested extensively with MC simulation before applying it to data. In the fits to the  $\geq 1$   $b$ -tag data, applying MC corrections to the 0  $b$ -tag background template increases the statistical uncertainty because of the uncertainty due to the number of simulated events but raises the measured cross section by only 1%.

Fig. 1 shows the BDT<sub>j</sub> (OS-SS) distributions of  $\ell + \tau$  events with 0  $b$ -tag and the 0  $b$ -tag background template after subtracting the expected number of  $\tau$  leptons and applying the MC corrections. The  $\tau$  signal is mostly  $Z \rightarrow \tau^+\tau^-$  events with a small contamination of electrons faking  $\tau$  leptons (from  $t\bar{t} \rightarrow \ell + e + X$  and  $Z \rightarrow e^+e^-$ ) and a small contribution from  $t\bar{t} \rightarrow \ell + \tau + X$ . The uncertainty on the background template includes the statistical uncertainty of the correction, the statistical uncertainty from MC and the 0  $b$ -tag data uncertainty.

Fig. 2 shows the result of the fit to the  $\geq 1$   $b$ -tag samples. The  $\tau$  lepton signal is mostly  $t\bar{t} \rightarrow \ell + \tau + X$  with a small contamination of misidentified electrons (estimated by applying fake probabilities derived from data), and small contributions from  $Z \rightarrow \tau^+\tau^-$  events and single top quark events (estimated from MC simulation). These contributions are subtracted from the number of fitted  $\tau$  lepton signal events before calculating the cross section. The fit results using the background templates derived from 0  $b$ -tag data and  $W + 1$  jet data are shown in Table 2. The results are consistent with each other within the statistical uncertainties of the background templates. The BDT<sub>j</sub> distributions for  $\tau_1$  and  $\tau_3$  are

**Table 2**

Results of template fits to  $\mu + \tau$ ,  $e + \tau$  and the combined  $BDT_j$  distributions. The combined results are obtained by fitting the sum of the  $\mu + \tau$  and  $e + \tau$   $BDT_j$  distributions. The first column gives the channel and the second the  $\tau$  type. The third column shows the extracted signal (sum of  $\tau$  leptons and electrons misidentified as  $\tau$  leptons) with the background template derived from 0  $b$ -tag data distributions. The fourth column shows the extracted signal with the background template derived from  $W + 1$  jet. The uncertainties are from the uncertainties in the fit parameters and do not include the systematic uncertainties. The MC columns give the expected  $\tau$  signal (includes the contribution of non- $t\bar{t} \rightarrow l + \tau$  events) and the expected number of  $t\bar{t} \rightarrow l + \tau$  assuming the theoretical  $t\bar{t}$  production cross section (164 pb).

		Background template		MC	
		0 $b$ -tag	$W + 1$ jet	Signal	$t\bar{t}$
$\mu + \tau$	$\tau_1$	$490 \pm 40$	$456 \pm 32$	432	388
	$\tau_3$	$135 \pm 33$	$130 \pm 50$	126	116
$e + \tau$	$\tau_1$	$440 \pm 50$	$430 \pm 50$	388	338
	$\tau_3$	$116 \pm 32$	$120 \pm 28$	114	101
Combined	$\tau_1$	$930 \pm 70$	$860 \pm 50$	820	726
	$\tau_3$	$260 \pm 60$	$260 \pm 40$	239	217

fitted separately. The combined  $\ell + \tau_i$  results are obtained by fitting the sum of the distributions. After adding  $\ell + \tau_1$  and  $\ell + \tau_3$  signals obtained from a  $\chi^2$  fit to the combined  $e + \tau$  and  $\mu + \tau$  distributions and subtracting the small contributions to the signal from  $Z \rightarrow \tau^+ \tau^-$ ,  $Z \rightarrow e^+ e^-$  and  $t\bar{t} \rightarrow e + \ell$  (given in Table 1), the results are  $840 \pm 70$  ( $243 \pm 60$ )  $t\bar{t} \rightarrow \ell + \tau_1(\tau_3) + X$  events. The uncertainty is from the fit only and does not include systematic uncertainties. The results are in good agreement with the  $780 \pm 50$  ( $243 \pm 60$ ) events obtained with the  $W + 1$  jet background template and consistent with the number expected from MC simulation,  $726 \pm 19$  ( $217 \pm 10$ ). Note that the fit uncertainty is dominated by the uncertainties on the background template, thus the statistical uncertainties of the results with the two different background templates are not strongly correlated.

Fig. 3 shows the OS-SS distribution of the number of jets for  $\geq 1$   $b$ -tag events adding all channels for two  $BDT_j$  regions:  $BDT_j < 0.7$ , which is dominated by  $t\bar{t} \rightarrow \ell + \text{jets}$ , and  $BDT_j > 0.7$ , in which the largest contribution is from  $t\bar{t} \rightarrow \ell + \tau + X$ . As expected, the multiplicity of jets peaks at four when  $BDT_j < 0.7$  and three when  $BDT_j > 0.7$  (the  $\tau$  is counted as a jet). Fig. 4 shows the invariant mass of a selected jet with the  $\tau$  candidate for  $BDT_j < 0.7$  and  $BDT_j > 0.7$  for events with a  $\tau$  candidate and three or more jets. The selected jet is the highest  $p_T$  untagged jet in events with more than one  $b$ -tag and the second highest  $p_T$  untagged jet in events with one  $b$ -tag. The distribution shows clearly the presence of a  $W$  decaying to two jets in the  $BDT_j < 0.7$  region dominated by  $t\bar{t} \rightarrow \ell + \text{jets}$ . The mass distribution in the  $BDT_j > 0.7$  signal region is significantly broader as expected for  $t\bar{t} \rightarrow \ell + \tau + X$ . The signal and background shown in these figures are based on the fit using the 0  $b$ -tag background template.

### 7.1. Check with matrix method

From Figs. 3 and 4 one can see that a  $BDT_j > 0.7$  requirement separates well a region dominated by  $t\bar{t} \rightarrow \ell + \text{jets}$  from a region dominated by  $t\bar{t} \rightarrow \ell + \tau + X$ . One can extract the signal from the same OS-SS  $\geq 1$   $b$ -tag sample used by the fit method via a matrix method. All  $\tau$  candidates are labelled “loose”, and  $\tau$  candidates with  $BDT_j > 0.7$  are labelled “tight”. The probability that the loose  $\tau$  candidates are also tight  $\tau$  candidates, for both  $\tau$  leptons and fake  $\tau$  leptons, is defined as

$$\epsilon_{\text{real}} = \frac{N_{\text{real}}^{\text{tight}}}{N_{\text{real}}^{\text{loose}}} \quad \epsilon_{\text{fake}} = \frac{N_{\text{fake}}^{\text{tight}}}{N_{\text{fake}}^{\text{loose}}}$$

Fig. 3. OS-SS number of jets distributions for events with at least one  $b$ -tag. The  $\mu + \tau$  and  $e + \tau$  channels have been summed together. The solid circles indicate the expected signal and backgrounds. The normalisation of the expected signal and the backgrounds are based on the fit result. The uncertainty includes statistical and systematic contributions. The fraction of each background is estimated from MC. (a) for  $BDT_j < 0.7$ , (b) for  $BDT_j > 0.7$ .

where the “real” subscript denotes  $\tau$  lepton, the “fake” subscript denotes fake  $\tau$  and  $N$  is the number of  $\tau$  candidates. The number of “tight”  $\tau$  leptons is then given by

$$N_{\text{real}}^{\text{tight}} = N_{\text{data}}^{\text{tight}} - \frac{\epsilon_{\text{fake}}}{\epsilon_{\text{real}} - \epsilon_{\text{fake}}} (N_{\text{data}}^{\text{loose}} \cdot \epsilon_{\text{real}} - N_{\text{data}}^{\text{tight}}).$$

The value of  $\epsilon_{\text{fake}}$  is measured utilising the OS-SS  $BDT_j$  distributions from the background control samples;  $\epsilon_{\text{real}}$  is derived from MC (including all processes that contribute a  $\tau$  lepton or an electron misidentified as a  $\tau$  lepton) and was tested using  $Z \rightarrow \tau^+ \tau^-$  events. This method uses the binning approach described in Section 6 to estimate the background. Values of  $\epsilon_{\text{fake}}$  and  $\epsilon_{\text{real}}$  are measured separately for three EM-fraction bins. The EM-fraction, the ratio of the energy measured in the EM calorimeter to the total  $\tau$  candidate energy measured in the calorimeter, is an effective variable for splitting the data into regions where the shapes of MC OS-SS  $BDT_j$  distributions for the  $W + 1$  jet background template and the  $\geq 1$   $b$ -tag background are similar. Table 3 shows the number of signal events obtained with the matrix method using the background derived from the 0  $b$ -tag data sample and from the  $W + 1$  jet data sample. The numbers in each pair are in good agreement and consistent with the numbers obtained by fitting the OS-SS  $BDT_j$  distributions.

### 7.2. Systematic uncertainty

Several experimental and theoretical sources of systematic uncertainty are considered. Lepton trigger, reconstruction and selection efficiencies are assessed by comparing the  $Z \rightarrow \ell^+ \ell^-$  events

**Fig. 4.** OS-SS invariant mass of jet and  $\tau$  candidate for events with at least one  $b$ -tag. The jet is the highest  $p_T$  untagged jet in events with more than one  $b$ -tag and the second highest  $p_T$  untagged jet in events with one  $b$ -tag. The  $\mu + \tau$  and  $e + \tau$  channels have been summed together. The solid circles indicate data and the histograms indicate the expected signal and backgrounds. The normalisation of the expected signal and the backgrounds are based on the fit result. The uncertainty includes statistical and systematic contributions. The fraction of each background is estimated from MC. (a) is for  $BDT_j < 0.7$ , (b) for  $BDT_j > 0.7$ .

**Table 3**

Number of signal events obtained with the matrix method for  $\mu + \tau$ ,  $e + \tau$  and the combined channels. The first column gives the channel and the second the  $\tau$  type. The third column shows the extracted signal with the background template derived from 0  $b$ -tag data distributions. The fourth column shows the extracted signal with the background template derived from  $W + 1$  jet. In order to compare the matrix method results to the fit results the number of signal events shown is  $\sum N_{\text{tight}}^{\text{real}} / \bar{\epsilon}_{\text{real}}$  where  $\bar{\epsilon}_{\text{real}}$  is the  $\epsilon_{\text{real}}$  averaged over the three EM-fraction bins. The uncertainties are statistical only.

		Background template	
		0 $b$ -tag	$W + 1$ jet
$\mu + \tau$	$\tau_1$	$460 \pm 50$	$440 \pm 50$
	$\tau_3$	$130 \pm 40$	$105 \pm 35$
$e + \tau$	$\tau_1$	$420 \pm 60$	$350 \pm 50$
	$\tau_3$	$140 \pm 40$	$160 \pm 40$
Combined	$\tau_1$	$880 \pm 70$	$800 \pm 70$
	$\tau_3$	$270 \pm 60$	$260 \pm 60$

selected with the same object criteria as used for the  $t\bar{t}$  analysis in data and MC.

Scale factors are applied to  $Z \rightarrow \tau^+\tau^-$  MC samples when calculating acceptances to account for any differences between predicted and observed efficiencies. The scale factors are evaluated by comparing the observed efficiencies with those determined with simulated  $Z$  boson events. Systematic uncertainties on these scale factors are evaluated by varying the selection of events used in the

**Table 4**

Relative systematic uncertainties, in %, for the cross-section measurement. The first column gives the source of systematic uncertainty, ID/Trigger stands for the combined uncertainty of lepton identification and lepton trigger. The  $\tau$  ID uncertainty includes electrons misidentified as  $\tau$  leptons. The second and third columns give the channel.

Source	$\mu + \tau$	$e + \tau$
$\mu$ (ID/Trigger)	$-1.1 / + 1.5$	–
$e$ (ID/Trigger)	–	$\pm 2.9$
JES	$-2.0 / + 2.2$	$-1.9 / + 2.8$
JER	$\pm 1.0$	$\pm 1.2$
ISR/FSR	$\pm 4.8$	$\pm 3.5$
Generator	$\pm 0.7$	$\pm 0.7$
PDF	$\pm 2.0$	$\pm 2.1$
$b$ -tag	$-7.7 / + 9.0$	$-7.5 / + 8.9$
$\tau_1$ ID	$-3.0 / + 3.2$	$-2.7 / + 3.0$
$\tau_3$ ID	$-3.1 / + 3.4$	$-2.9 / + 3.2$

efficiency measurements and by checking the stability of the measurements over the course of data taking.

The modelling of the lepton momentum scale and resolution is studied using reconstructed invariant mass distributions of  $Z \rightarrow \ell^+\ell^-$  candidate events and used to adjust the simulation accordingly [34,35].

The jet energy scale (JES) and its uncertainty are derived by combining information from test-beam data, LHC collision data and simulation [32]. For jets within the acceptance, the JES uncertainty varies in the range 4–8% as a function of jet  $p_T$  and  $\eta$ . Comparing MC and data the estimated systematic uncertainties are 10% and 1–2% for the jet energy resolution (JER) and the jet reconstruction efficiency, respectively. The uncertainty on the efficiency of the  $b$ -tagging algorithm has been estimated to be 6% for  $b$ -quark jets, based on  $b$ -tagging calibration studies [33].

The uncertainty in the kinematic distributions of the  $t\bar{t}$  signal events gives rise to systematic uncertainties in the signal acceptance, with contributions from the choice of generator, the modelling of initial- and final-state radiation (ISR/FSR) and the choice of the PDF set. The generator uncertainty is evaluated by comparing the MC@NLO predictions with those of POWHEG [36–38] interfaced to either HERWIG or PYTHIA. The uncertainty due to ISR/FSR is evaluated using the ACERMC generator [39] (which relies on the MADGRAPH package [40]) interfaced to the PYTHIA shower model, and by varying the parameters controlling ISR and FSR in a range consistent with experimental data [19]. Finally, the PDF uncertainty is evaluated using a range of current PDF sets: NNPDF, CTEQ, and MSTW [41–43]. Each one comes with a set of error PDFs, the RMS of the variations was taken as the PDF uncertainty. The dominant uncertainty in this category of systematic uncertainties is the modelling of ISR/FSR.

The  $\tau$  ID uncertainty is derived from a template fit to a  $Z \rightarrow \tau^+\tau^-$  data sample selected with the same  $\mu$  and  $\tau$  candidate requirements as the sample for this analysis, but with fewer than two jets and  $m_T < 20$  GeV to remove  $W +$  jets events. The fit relies on the  $W + 1$  jet data sample for a background template and  $Z \rightarrow \tau^+\tau^-$  MC events for a signal template. The uncertainty includes the statistical uncertainty of the data samples, the uncertainty in the  $Z/\gamma^*$  cross section measured by ATLAS [44] (excluding the luminosity uncertainty) and the jet energy scale uncertainty. It also includes the uncertainty on the number of misidentified electrons (<0.5%, determined from  $Z \rightarrow e^+e^-$  data).

The effect of these variations on the final result is evaluated by varying each source of systematic uncertainty by  $\pm 1\sigma$ , applying the selection criteria to obtain new signal and background templates and recalculating the cross section.

**Table 5**

Measured cross section from the  $\tau_1$  and  $\tau_3$  samples, as well as the combination ( $\tau_1 + \tau_3$ ) for each channel separately. The uncertainty in the integrated luminosity (3.7%) is not included.

$\mu + \tau$	
$\tau_1$	$189 \pm 16$ (stat.) $\pm 20$ (syst.) pb
$\tau_3$	$180 \pm 40$ (stat.) $\pm 21$ (syst.) pb
$\tau_1 + \tau_3$	$186 \pm 15$ (stat.) $\pm 20$ (syst.) pb
$e + \tau$	
$\tau_1$	$190 \pm 20$ (stat.) $\pm 20$ (syst.) pb
$\tau_3$	$170 \pm 50$ (stat.) $\pm 21$ (syst.) pb
$\tau_1 + \tau_3$	$187 \pm 18$ (stat.) $\pm 20$ (syst.) pb

The uncertainties obtained for the fit method using the 0  $b$ -tag background template are shown in Table 4. The systematic uncertainties for the matrix method are very similar. The uncertainty on the measured integrated luminosity is 3.7% [45]. This translates into a 3.5% uncertainty on the cross section.

## 8. Measuring the $t\bar{t}$ cross section

The cross section is derived from the number of observed OS-SS signal events in the  $\geq 1$   $b$ -tag data sample assuming the only top quark decay mode is  $t \rightarrow W b$ , and subtracting from that number the small contribution from  $t\bar{t} \rightarrow e + \ell$  (from electrons faking  $\tau$  leptons) and  $\tau$  leptons from  $Z \rightarrow \tau^+ \tau^-$  (Table 1). The systematic uncertainties are estimated as the quadratic sum of all uncertainties given in Table 4, which includes the uncertainty from the subtraction.

The results are given separately for  $\tau_1$  and  $\tau_3$  and then combined (weighted by their statistical uncertainty and assuming all systematic uncertainties other than from  $\tau$  ID are fully correlated). The results using the 0  $b$ -tag background template are shown in Table 5.

The results for the  $\mu + \tau$  and  $e + \tau$  channels are combined taking into account the correlated uncertainties using the BLUE (Best Linear Unbiased Estimator) technique [46]. Combining them does not improve the systematic uncertainty as the systematic uncertainties are almost 100% correlated.

The results for each lepton type are:

$$\mu + \tau: \sigma_{t\bar{t}} = 186 \pm 15 \text{ (stat.)} \pm 20 \text{ (syst.)} \pm 7 \text{ (lumi.) pb},$$

$$e + \tau: \sigma_{t\bar{t}} = 187 \pm 18 \text{ (stat.)} \pm 20 \text{ (syst.)} \pm 7 \text{ (lumi.) pb},$$

Combining both channels one obtains:

$$\sigma_{t\bar{t}} = 186 \pm 13 \text{ (stat.)} \pm 20 \text{ (syst.)} \pm 7 \text{ (lumi.) pb}.$$

To check the fit measurements, the cross sections can be calculated using the matrix method and the results obtained with the  $W + 1$  jet background to minimise the correlation with the fit results. The combination of the matrix method and the fit results with the BLUE method shows they are compatible at the 45% and 10% confidence level for  $\mu + \tau$  and  $e + \tau$ , respectively.

## 9. Conclusions

The cross section for  $t\bar{t}$  production in  $pp$  collisions at 7 TeV has been measured in the  $\mu + \tau$  and the  $e + \tau$  channels in which the  $\tau$  decays hadronically. The number of  $\tau$  leptons in these channels has been extracted using multivariate discriminators to separate  $\tau$  leptons from electrons and jets misidentified as hadronically decaying  $\tau$  leptons. These numbers were obtained by fitting the discriminator outputs and checked with a matrix method. Combining the measurements from  $\mu + \tau$  and  $e + \tau$  events, the cross

section is measured to be

$$\sigma_{t\bar{t}} = 186 \pm 13 \text{ (stat.)} \pm 20 \text{ (syst.)} \pm 7 \text{ (lumi.) pb},$$

in good agreement with the cross section measured by ATLAS in other channels [1,2], with the cross-section measurements by the CMS Collaboration [3–5,7] and with the SM prediction,  $164^{+11}_{-16}$  pb [25].

## Acknowledgements

We thank CERN for the very successful operation of the LHC, as well as the support staff from our institutions without whom ATLAS could not be operated efficiently.

We acknowledge the support of ANPCyT, Argentina; YerPhI, Armenia; ARC, Australia; BMWF, Austria; ANAS, Azerbaijan; SSTC, Belarus; CNPq and FAPESP, Brazil; NSERC, NRC and CFI, Canada; CERN; CONICYT, Chile; CAS, MOST and NSFC, China; COLCIENCIAS, Colombia; MSMT CR, MPO CR and VSC CR, Czech Republic; DNRF, DNSRC and Lundbeck Foundation, Denmark; EPLANET and ERC, European Union; IN2P3-CNRS, CEA-DSM/IRFU, France; GNAS, Georgia; BMBF, DFG, HGF, MPG and AvH Foundation, Germany; GSRT, Greece; ISF, MINERVA, GIF, DIP and Benoziyo Center, Israel; INFN, Italy; MEXT and JSPS, Japan; CNRST, Morocco; FOM and NWO, Netherlands; RCN, Norway; MNiSW, Poland; GRICES and FCT, Portugal; MERYS (MECTS), Romania; MES of Russia and ROSATOM, Russian Federation; JINR; MSTD, Serbia; MSSR, Slovakia; ARRS and MVZT, Slovenia; DST/NRF, South Africa; MICINN, Spain; SRC and Wallenberg Foundation, Sweden; SER, SNSF and Cantons of Bern and Geneva, Switzerland; NSC, Taiwan; TAEK, Turkey; STFC, the Royal Society and Leverhulme Trust, United Kingdom; DOE and NSF, United States of America.

The crucial computing support from all WLCG partners is acknowledged gratefully, in particular from CERN and the ATLAS Tier-1 facilities at TRIUMF (Canada), NDGF (Denmark, Norway, Sweden), CC-IN2P3 (France), KIT/GridKA (Germany), INFN-CNAF (Italy), NL-T1 (Netherlands), PIC (Spain), ASGC (Taiwan), RAL (UK) and BNL (USA) and in the Tier-2 facilities worldwide.

<sup>148</sup> Departments of Physics & Astronomy and Chemistry, Stony Brook University, Stony Brook, NY, United States  
<sup>149</sup> Department of Physics and Astronomy, University of Sussex, Brighton, United Kingdom  
<sup>150</sup> School of Physics, University of Sydney, Sydney, Australia

- 151 Institute of Physics, Academia Sinica, Taipei, Taiwan  
 152 Department of Physics, Technion: Israel Inst. of Technology, Haifa, Israel  
 153 Raymond and Beverly Sackler School of Physics and Astronomy, Tel Aviv University, Tel Aviv, Israel  
 154 Department of Physics, Aristotle University of Thessaloniki, Thessaloniki, Greece  
 155 International Center for Elementary Particle Physics and Department of Physics, The University of Tokyo, Tokyo, Japan  
 156 Graduate School of Science and Technology, Tokyo Metropolitan University, Tokyo, Japan  
 157 Department of Physics, Tokyo Institute of Technology, Tokyo, Japan  
 158 Department of Physics, University of Toronto, Toronto, ON, Canada  
 159 <sup>(a)</sup>TRIUMF, Vancouver BC; <sup>(b)</sup>Department of Physics and Astronomy, York University, Toronto, ON, Canada  
 160 Institute of Pure and Applied Sciences, University of Tsukuba, 1-1-1 Tenuodai, Tsukuba, Ibaraki 305-8571, Japan  
 161 Science and Technology Center, Tufts University, Medford, MA, United States  
 162 Centro de Investigaciones, Universidad Antonio Narino, Bogota, Colombia  
 163 Department of Physics and Astronomy, University of California Irvine, Irvine, CA, United States  
 164 <sup>(a)</sup>INFN Gruppo Collegato di Udine; <sup>(b)</sup>ICTP, Trieste; <sup>(c)</sup>Dipartimento di Chimica, Fisica e Ambiente, Università di Udine, Italy  
 165 Department of Physics, University of Illinois, Urbana, IL, United States  
 166 Department of Physics and Astronomy, University of Uppsala, Uppsala, Sweden  
 167 Instituto de Física Corpuscular (IFIC) and Departamento de Física Atómica, Molecular y Nuclear and Departamento de Ingeniería Electrónica and Instituto de Microelectrónica de Barcelona (IMB-CNM), University of Valencia and CSIC, Valencia, Spain  
 168 Department of Physics, University of British Columbia, Vancouver, BC, Canada  
 169 Department of Physics and Astronomy, University of Victoria, Victoria, BC, Canada  
 170 Department of Physics, University of Warwick, Coventry, United Kingdom  
 171 Waseda University, Tokyo, Japan  
 172 Department of Particle Physics, The Weizmann Institute of Science, Rehovot, Israel  
 173 Department of Physics, University of Wisconsin, Madison, WI, United States  
 174 Fakultät für Physik und Astronomie, Julius-Maximilians-Universität, Würzburg, Germany  
 175 Fachbereich C Physik, Bergische Universität Wuppertal, Wuppertal, Germany  
 176 Department of Physics, Yale University, New Haven, CT, United States  
 177 Yerevan Physics Institute, Yerevan, Armenia  
 178 Domaine scientifique de la Doua, Centre de Calcul CNRS/IN2P3, Villeurbanne Cedex, France

<sup>a</sup> Also at Laboratorio de Instrumentacao e Fisica Experimental de Particulas – LIP, Lisboa, Portugal.

<sup>b</sup> Also at Faculdade de Ciencias and CFNUL, Universidade de Lisboa, Lisboa, Portugal.

<sup>c</sup> Also at Particle Physics Department, Rutherford Appleton Laboratory, Didcot, United Kingdom.

<sup>d</sup> Also at TRIUMF, Vancouver, BC, Canada.

<sup>e</sup> Also at Department of Physics, California State University, Fresno, CA, United States.

<sup>f</sup> Also at Novosibirsk State University, Novosibirsk, Russia.

<sup>g</sup> Also at Fermilab, Batavia, IL, United States.

<sup>h</sup> Also at Department of Physics, University of Coimbra, Coimbra, Portugal.

<sup>i</sup> Also at Università di Napoli Parthenope, Napoli, Italy.

<sup>j</sup> Also at Institute of Particle Physics (IPP), Canada.

<sup>k</sup> Also at Department of Physics, Middle East Technical University, Ankara, Turkey.

<sup>l</sup> Also at Louisiana Tech University, Ruston, LA, United States.

<sup>m</sup> Also at Department of Physics and Astronomy, University College London, London, United Kingdom.

<sup>n</sup> Also at Group of Particle Physics, University of Montreal, Montreal, QC, Canada.

<sup>o</sup> Also at Department of Physics, University of Cape Town, Cape Town, South Africa.

<sup>p</sup> Also at Institute of Physics, Azerbaijan Academy of Sciences, Baku, Azerbaijan.

<sup>q</sup> Also at Institut für Experimentalphysik, Universität Hamburg, Hamburg, Germany.

<sup>r</sup> Also at Manhattan College, New York, NY, United States.

<sup>s</sup> Also at School of Physics, Shandong University, Shandong, China.

<sup>t</sup> Also at CPPM, Aix-Marseille Université and CNRS/IN2P3, Marseille, France.

<sup>u</sup> Also at School of Physics and Engineering, Sun Yat-sen University, Guangzhou, China.

<sup>v</sup> Also at Academia Sinica Grid Computing, Institute of Physics, Academia Sinica, Taipei, Taiwan.

<sup>w</sup> Also at Dipartimento di Fisica, Università La Sapienza, Roma, Italy.

<sup>x</sup> Also at DSM/IRFU (Institut de Recherches sur les Lois Fondamentales de l'Univers), CEA Saclay (Commissariat à l'Energie Atomique), Gif-sur-Yvette, France.

<sup>y</sup> Also at Section de Physique, Université de Genève, Geneva, Switzerland.

<sup>z</sup> Also at Departamento de Física, Universidade de Minho, Braga, Portugal.

<sup>aa</sup> Also at Department of Physics and Astronomy, University of South Carolina, Columbia, SC, United States.

<sup>ab</sup> Also at Institute for Particle and Nuclear Physics, Wigner Research Centre for Physics, Budapest, Hungary.

<sup>ac</sup> Also at California Institute of Technology, Pasadena, CA, United States.

<sup>ad</sup> Also at Institute of Physics, Jagiellonian University, Krakow, Poland.

<sup>ae</sup> Also at LAL, Univ. Paris-Sud and CNRS/IN2P3, Orsay, France.

<sup>af</sup> Also at Department of Physics and Astronomy, University of Sheffield, Sheffield, United Kingdom.

<sup>ag</sup> Also at Department of Physics, Oxford University, Oxford, United Kingdom.

<sup>ah</sup> Also at Institute of Physics, Academia Sinica, Taipei, Taiwan.

<sup>ai</sup> Also at Department of Physics, The University of Michigan, Ann Arbor, MI, United States.

\* Deceased.
