Measurements of the pseudorapidity dependence of the total transverse energy in proton-proton collisions at $\sqrt{s} = 7$ TeV with ATLAS

The ATLAS Collaboration

Abstract

This paper describes measurements of the sum of the transverse energy of particles as a function of particle pseudorapidity, η , in proton-proton collisions at a centre-of-mass energy, $\sqrt{s} = 7$ TeV using the ATLAS detector at the Large Hadron Collider. The measurements are performed in the region $|\eta| < 4.8$ for two event classes: those requiring the presence of particles with a low transverse momentum and those requiring particles with a significant transverse momentum. In the second dataset measurements are made in the region transverse to the hard scatter. The distributions are compared to the predictions of various Monte Carlo event generators, which generally tend to underestimate the amount of transverse energy at high $|\eta|$.

1 Introduction

The main aim of the Large Hadron Collider (LHC) general-purpose detectors is to explore physics in collisions around and above the electroweak symmetry-breaking scale. Such processes typically involve high momentum transfer, which distinguishes them from the dominant processes, namely low momentum transfer strong force interactions described by non-perturbative Quantum Chromodynamics (QCD). In order to collect enough data

to be sensitive to rare processes it is necessary to run the LHC at high instantaneous luminosities, meaning that multiple proton-proton interactions are very likely to occur each time the proton bunches collide. It is essential that the Monte Carlo event generators used to simulate these processes have an accurate description of the soft particle kinematics in inclusive proton-proton interactions over the entire acceptance of the LHC experiments, such that reliable comparisons can be made between theoretical predictions and the data for any process of interest.

Protons are composite objects made up of partons, the longitudinal momentum distributions of which are described by parton distribution functions (PDFs). When protons interact at the LHC the dominant parton-parton interaction is t -channel gluon exchange. Due to the composite nature of the protons it is possible that multiple parton-parton interactions (MPI) occur in the same proton-proton interaction. Therefore, if a hard parton-parton interaction occurs it will likely be accompanied by additional QCD interactions, again predominately low momentum t -channel gluon exchange. Any part of the interaction not attributed to the hard parton-parton scatter is collectively termed the underlying event, which includes MPI as well as soft particle production from the beam-beam remnants. Monte Carlo event generators that simulate any hard process at the LHC must also include an accurate description of the underlying event.

At low momentum transfer, perturbative calculations in QCD are not meaningful and cross-sections cannot currently be computed from first principles. Phenomenological models are therefore used to describe the kinematics of particle production in inclusive proton-proton interactions and in the underlying event in events with a hard scatter; these must be constrained by, and tuned to, data.

This paper presents a measurement of the sum of the transverse energy, ΣE_T , of particles produced in proton-proton collisions at the LHC, using the ATLAS detector [1]. The ΣE_T distribution is measured in bins of pseudorapidity¹, η , in the range $|\eta| < 4.8$. Distributions of the ΣE_T and the mean ΣE_T as a function of $|\eta|$ are presented. These measurements are performed with two distinct datasets. The first is as inclusive as possible, with minimal event selection applied, sufficient to ensure that an inelastic collision has occurred. This is termed the *minimum bias* dataset and is studied in order to probe the particle kinematics in inclusive proton-proton interactions. Understanding these processes is vital to ensure a good description of multiple proton-proton interactions in runs with high instantaneous luminosity. The second dataset requires the presence of two jets with high transverse energy, $E_T > 20$ GeV, which ensures a hard parton-parton scatter has occurred and therefore allows the particle kinematics in the underlying event to be probed. This sample is termed the *dijet* dataset. Both datasets were collected during the first LHC runs at $\sqrt{s} = 7$ TeV in 2010. The data samples correspond to integrated luminosities of $7.1 \mu\text{b}^{-1}$

¹ATLAS uses a right-handed coordinate system with its origin at the nominal interaction point (IP) in the centre of the detector and the z -axis along the beam pipe. The x -axis points from the IP to the centre of the LHC ring, and the y -axis points upward. Cylindrical coordinates (r, ϕ) are used in the transverse ($x - y$) plane, ϕ being the azimuthal angle around the beam pipe. The pseudorapidity is defined in terms of the polar angle θ with respect to the beamline as $\eta = -\ln \tan(\theta/2)$.

for the minimum bias measurement² and $590 \mu\text{b}^{-1}$ for the dijet measurement. Such small data samples are used because the early LHC runs had a very low instantaneous luminosity ensuring a negligible contribution from multiple proton-proton interactions. The larger sample for the dijet analysis is used as the cross-section for a hard scatter is significantly lower than for inclusive proton-proton interactions.

Many previous measurements of the kinematic properties of particles produced in minimum bias events [2–5] and in the underlying event [6–11] were restricted to the central region of the detectors. This is because they used tracking detectors, with limited coverage, to study charged particles, or because they used only the central region of the calorimeters, where the tracking detectors could be used for calibration. Measurements of the mean of the sum of the energy of particles as a function of $|\eta|$ in minimum bias events and in the underlying event were performed with the CMS forward calorimeter [12]; these were limited to the very forward region ($3.15 < |\eta| < 4.9$). LHCb has performed measurements of charged particle multiplicities in the regions $-2.5 < \eta < -2.0$ and $2.0 < \eta < 4.5$ [13].

The measurements described in this paper utilize the entire acceptance of the ATLAS calorimeters, $|\eta| < 4.9$, allowing the ΣE_T to be probed and unfolded in the region $|\eta| < 4.8$. Unless otherwise stated, the central region will refer to the range $|\eta| < 2.4$ and the forward region will refer to the range $2.4 < |\eta| < 4.8$. The measurement is performed with the ATLAS calorimeters and is corrected for detector effects so that the variables are defined at the particle-level (see Section 2), which includes all stable particles (those with a proper lifetime greater than 3×10^{-11} seconds). Both the mean and distributions of the ΣE_T are measured. This provides additional information, giving a complete picture of both inclusive proton-proton interactions and the underlying event in dijet processes, within the entire acceptance of the general purpose LHC detectors. The relative levels of particle production in the forward and central regions may be affected by the contribution from beam-beam remnant interactions, details of the hadronization as modelled with colour reconnection between quarks and gluons, the relative contribution from diffractive processes and the parton distribution functions in this kinematic domain.

This paper is organized as follows. Section 2 defines the particle-level variables. Section 3 describes the Monte Carlo models that are used to correct the data for detector effects and to compare to the final unfolded results. The ATLAS detector is discussed in section 4, the event reconstruction in section 5 and the event selection in section 6. The method used to correct the data for detector effects is described in section 7. The systematic uncertainties are described in section 8. Section 9 presents and discusses the final results and compares them to various Monte Carlo simulations. Finally, conclusions are given in section 10.

2 Particle-level variable definitions

In data, events are selected and variables defined using calibrated detector-level quantities. Corrections for detector effects are then applied. In order to compare the corrected data with predictions from Monte Carlo event generators without passing the events through

²The run dependence of the analysis was checked in a larger sample and found to be negligible.

a simulation of the ATLAS detector, it is necessary to define variables at the particle-level. The particle-level ΣE_T is defined at the generator level by summing the E_T of all stable charged particles with momentum $p > 500$ MeV and all stable neutral particles with $p > 200$ MeV. Lower momentum particles are not included as they are unlikely to deposit significant energy in the ATLAS calorimeters.

The ΣE_T distribution is defined as $\frac{1}{N_{\text{evt}}} \frac{dN_{\text{evt}}}{d\Sigma E_T}$, where N_{evt} is the number of events in the sample. It is measured in six regions: $0.0 < |\eta| < 0.8$, $0.8 < |\eta| < 1.6$, $1.6 < |\eta| < 2.4$, $2.4 < |\eta| < 3.2$, $3.2 < |\eta| < 4.0$ and $4.0 < |\eta| < 4.8$. In addition the mean ΣE_T over all events, per unit η - ϕ , is measured as a function of $|\eta|$. This is denoted as the transverse energy density (E_T^{density}) and is defined as $\langle \frac{d^2 \Sigma E_T}{d\eta d\phi} \rangle$. In the minimum bias measurement, the ΣE_T includes particles at any ϕ . In the dijet measurement, the ΣE_T is measured using only particles that are in the azimuthal region transverse to the hard scatter, namely $\frac{\pi}{3} < |\Delta\phi| < \frac{2\pi}{3}$, where $\Delta\phi$ is the azimuthal separation between the leading jet and a given particle. This region of phase space contains limited particle production from the hard parton-parton interaction and is therefore most sensitive to the underlying event.

2.1 Particle-level minimum bias event selection

The events in the minimum bias analysis contain at least two charged particles with $p_T > 250$ MeV and $|\eta| < 2.5$, reflecting as closely as possible the requirement of a reconstructed vertex, as will be discussed in section 6.

2.2 Particle-level dijet event selection

The events in the dijet analysis contain at least two particle-level jets³. Both the leading and sub-leading jets must have $E_T^{\text{jet}} > 20$ GeV and $|\eta^{\text{jet}}| < 2.5$, reconstructed with the anti- k_t [14] algorithm with radius parameter $R = 0.4$. This selection ensures that a hard scattering has occurred. A relatively small radius parameter reduces the probability of the jet algorithm collecting particles that are not associated with the hard scatter. In order to select a well balanced back-to-back dijet system, the jets satisfy $|\Delta\phi_{jj}| > 2.5$ radians, where $\Delta\phi_{jj}$ is the difference in azimuthal angle of the leading and sub-leading jet, and $\frac{E_T^{\text{jet}2}}{E_T^{\text{jet}1}} > 0.5$, where $E_T^{\text{jet}1(2)}$ is the E_T of the (sub-)leading jet. The latter requirement retains most of the dataset, but avoids topologies in which there is a large transverse energy difference between the leading and sub-leading jets. A well balanced dijet system suppresses contributions from multijet events, allowing a clearer distinction between regions with particle production dominated by the hard scatter and by the underlying event.

3 Monte Carlo event generators

This section describes the Monte Carlo event generator (MC) models used to correct the data for detector effects, to assign systematic uncertainties to the corrections due to the physics model, and for comparisons with the final unfolded data. The PYTHIA 6 [15], PYTHIA 8 [16], Herwig++ [17] and EPOS [18] generators are used, with various tunes that are

³A particle-level jet is built from all stable particles, excluding neutrinos and muons.

described below. First a brief introduction to the relevant parts of the event generators is given.

PYTHIA 6 and **PYTHIA 8** are general purpose generators that use the Lund string hadronization model [19]. In **PYTHIA 6** there is an option to use a virtuality-ordered or p_T -ordered parton shower, with the latter used in most recent tunes. In **PYTHIA 8**, the p_T -ordered parton shower is used. The inclusive hadron-hadron interactions are described by a model that splits the total inelastic cross-section into non-diffractive processes, dominated by t -channel gluon exchange, and diffractive processes involving a colour-singlet exchange. The diffractive processes are further divided into single-diffractive dissociation, where one of the initial hadrons remains intact and the other is diffractively excited and dissociates, and double-diffractive dissociation where both hadrons dissociate. Such events tend to have large gaps in particle production at central rapidity. The smaller contribution from central diffraction, in which both hadrons remain intact and particles are produced in the central region, is neglected. The $2 \rightarrow 2$ non-diffractive processes, including MPI, are described by lowest-order perturbative QCD with the divergence of the cross-section as $p_T \rightarrow 0$ regulated with a phenomenological model. There are many tunable parameters that control, among other things, the behaviour of this regularization, the matter distribution of partons within the hadrons, and colour reconnection. When p_T -ordered parton showers are used, the MPI and parton shower are interleaved in one common sequence of decreasing p_T values. For **PYTHIA 6** the interleaving is between the initial-state shower and MPI only, while for **PYTHIA 8** it also includes final-state showers. Since the p_T -ordered showers and interleaving with MPI are considered to be a model improvement, the most recent **PYTHIA 6** tunes are made with this configuration. This is also the only configuration available in **PYTHIA 8**. A pomeron-based approach is used to describe diffractive events, using (by default) the Schuler and Sjöstrand [20] parameterization of the pomeron flux. In **PYTHIA 6** the diffractive dissociations are treated using the Lund string model, producing final-state particles with limited p_T . In **PYTHIA 8** the dissociations are treated like this only for events with a diffractive system with a very low mass; in higher mass systems diffractive parton distributions from H1 [21] are used to include diffractive final states which are characteristic of hard partonic interactions. In this case, the full machinery of MPI and parton showers is used. This approach yields a significantly harder p_T spectrum for final-state particles.

Herwig++ is another general purpose generator, but with a different approach: it uses an angular-ordered parton shower and the cluster hadronization model [22]. It has an MPI model similar to the one used by the **PYTHIA** generators, with tunable parameters for regularizing the behaviour at very low momentum transfer, but does not include the interleaving with the parton showers. Inclusive hadron-hadron collisions are simulated by applying the MPI model to events with no hard scattering. It is therefore possible to generate an event with zero $2 \rightarrow 2$ partonic scatters, in which only beam remnants are produced, with nothing in between them. While **Herwig++** has no explicit model for diffractive processes, these zero-scatter events will look similar to double-diffractive dissociation.

EPOS is an event generator used primarily to simulate heavy ion and cosmic shower interactions, but which can also simulate proton-proton interactions. **EPOS** provides an

implementation of a parton based Gribov-Regge [23] theory which is an effective, QCD-inspired field theory describing hard and soft scattering simultaneously. EPOS calculations thus do not rely on the standard PDFs as used in generators like PYTHIA and Herwig++. At high parton densities a hydrodynamic evolution of the initial state is calculated for the proton-proton scattering process as it would be for heavy ion interactions. The results presented here use the EPOS LHC tune, which contains a parameterized approximation of the hydrodynamic evolution. The optimal parameterization has been derived from tuning to LHC minimum bias data.

The reference MC sample used throughout this study is the AMBT1 [24] tune of PYTHIA 6. In order to check the model dependence of the data corrections, additional generators and tunes are considered. These are summarized in table 1 along with information about the PDFs used and whether minimum bias or underlying event data at $\sqrt{s} = 7$ TeV were used in the tune. Of the PYTHIA 6 tunes listed, only DW uses the old virtuality-ordered parton shower without interleaving with MPI. Some more recent tunes are also used to compare to the unfolded data; these are summarized in table 2. For these more recent tunes the PDF is explicitly given in the name as there are different instances of each tune that use different PDFs and hence have different parameters.

4 The ATLAS detector

The ATLAS detector is described in detail in ref. [1]. Here only the components most relevant for this measurement are described.

Tracks and interaction vertices are reconstructed with the inner detector tracking system, which consists of a silicon pixel detector, a silicon strip detector and a transition radiation tracker, all immersed in a 2 T axial magnetic field. The calorimeter systems are of particular importance for the measurements presented in this paper. The ATLAS calorimeter system provides fine-grained measurements of shower energy depositions over a wide range of η . A highly segmented electromagnetic liquid argon (LAr) sampling calorimeter covers the region $|\eta| < 3.2$, with granularity that ranges from 0.003×0.10 or 0.025×0.025 to 0.1×0.1 in $\Delta\eta \times \Delta\phi$, depending on depth segment and pseudorapidity. It is divided into a barrel part ($|\eta| < 1.475$) and an endcap part ($1.375 < |\eta| < 3.2$). The hadronic barrel ($|\eta| < 1.7$) calorimeter consists of steel absorbers and active scintillating tiles, with a granularity of either 0.1×0.1 or 0.2×0.1 depending on the layer. The hadronic endcap ($1.5 < |\eta| < 3.2$) and forward ($3.1 < |\eta| < 4.9$) electromagnetic and hadronic calorimeters use liquid argon technology. The granularity in the hadronic endcap ranges from 0.1×0.1 to 0.2×0.2 . In the forward calorimeter, the cells are not arranged in projective towers but are aligned parallel to the beam axis. As such the readout granularity is not constant in $\eta-\phi$.

Minimum bias trigger scintillator (MBTS) detectors are mounted in front of the endcap calorimeters on both sides of the interaction point and cover the region $2.1 < |\eta| < 3.8$. The MBTS is divided into inner and outer rings, both of which have eight-fold segmentation, and is used to trigger the events analysed in this paper.

5 Event reconstruction

This analysis is based on topological clusters in the calorimeter, which represent an attempt to reconstruct three-dimensional energy depositions associated with individual particles [35]. The topological clustering algorithm proceeds through the following steps. First, seed cells are found that have $|E| > 4\sigma$ above the noise level, where E is the cell energy measured at the electromagnetic scale⁴ and calibrated using test-beam data [36–39]. Next, neighbouring cells are collected into the cluster if they have $|E| > 2\sigma$ above the noise level. Finally, all surrounding cells are added to the cluster until no further cells with $|E| > 2\sigma$ are among the direct neighbours.

The detector-level ΣE_T is formed by summing the E_T of all clusters in the $\eta-\phi$ region of interest. Negative energy clusters are included, leading to a convenient cancellation of the contributions from noise, which can be either negative or positive.

To correct these clusters back to the particle-level, it is first necessary to determine the particle momenta to which the ATLAS calorimeters are sensitive. Using a GEANT4 [40] sim-

⁴ The electromagnetic scale is the basic calorimeter signal scale for the ATLAS calorimeters. It gives the correct response for the energy deposited in electromagnetic showers, but does not account for the lower response to hadrons.

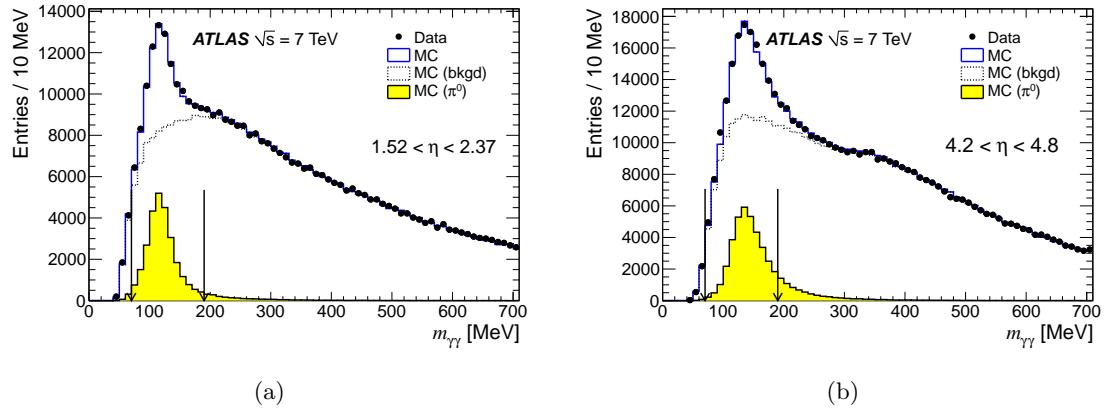

Figure 1. The di-photon invariant mass in the region (a) $1.52 < \eta < 2.37$ and (b) $4.2 < \eta < 4.8$. The data are compared to the MC simulation with the best fit scale factor applied (this is 0.97 ± 0.02 for (a) and 1.01 ± 0.02 for (b)). The contribution from the MC signal $\pi^0 \rightarrow \gamma\gamma$ templates and background templates are also shown separately. The arrows indicate the fit range.

ulation of the ATLAS detector [41], generator-level particles are propagated from the primary vertex to the calorimeters and the fraction of their energy deposited in the calorimeters as clusters is studied as a function of $|\eta|$ and p of the particle. As discussed in section 2, charged particles with $p > 500$ MeV and neutral particles with $p > 200$ MeV are found to deposit enough energy in the calorimeter to be included in the particle-level definition for all $|\eta|$ regions. Particles with lower momenta contribute a negligible amount to the cluster ΣE_T and are therefore excluded from the particle-level ΣE_T definition.

In order to properly correct for detector effects, the detector simulation must accurately describe the energy response of the calorimeters to low energy particles. The simulation calibration is refined using the di-photon invariant mass distribution of $\pi^0 \rightarrow \gamma\gamma$ candidates. In data selected with the MBTS trigger, pairs of photon candidates in a given η region are formed and their invariant mass, $m_{\gamma\gamma}$, is constructed. In order to reduce combinatorial background, only events with exactly one pair in the η region are considered. The data are compared to MC signal plus background templates in η bins, which are chosen to reflect the boundaries of the calorimeter sub-systems.

The signal templates are derived from the PYTHIA 6 AMBT1 samples, by matching pairs of clusters to generator level photons from a π^0 decay. The background templates are obtained using pairs of clusters that are not matched. The energies of the clusters in the signal template are scaled by an energy response scale factor. This is varied and the χ^2 between the data and MC distributions is minimized in order to determine the best fit value. Deviations from unity are typically 2–3% but reach values of up to 10% in some η regions. This scale factor is then applied to the energy of the MC clusters before unfolding the data. Figure 1 shows the $m_{\gamma\gamma}$ distribution in data compared to the MC in two sample $|\eta|$ regions with the best fit scale factor applied.

6 Event selection

Events in the minimum bias analysis are selected with a one-sided MBTS trigger, which requires one counter on either side of the detector to be above noise threshold, suppressing contributions from empty beam crossings and beam-induced background. In order to suppress these contributions further, events are required to have a reconstructed primary vertex with at least two associated tracks with $p_T > 150$ MeV and $|\eta| < 2.5$. Note that the track p_T cut is lower than the 250 MeV particle-level cut described in section 2.1. This is because tracking and vertex reconstruction inefficiencies result in events with at least two 150 MeV reconstructed tracks having the same E_T^{density} as events with at least two 250 MeV charged particles, according to the MC models considered in this analysis.

Furthermore, events having more than one reconstructed vertex with five or more tracks are vetoed to suppress contributions from multiple proton-proton interactions. Five tracks are required on the additional vertices so that events with secondary vertices from decaying particles are not vetoed.

Events in the dijet analysis are also selected with the one-sided MBTS trigger and are required to pass the same event selection criteria as the minimum bias analysis. In addition, they are required to contain two back-to-back jets passing the same kinematic selection criteria as the particle-level jets described in section 2.2.

7 Corrections for detector effects

The ΣE_T distributions are unfolded in each $|\eta|$ region using an iterative Bayesian unfolding technique [42]. The E_T^{density} distribution is obtained by taking the mean of each unfolded ΣE_T distribution and dividing by the $|\eta|$ and ϕ phase space. An unfolding matrix is formed from events generated with PYTHIA 6 AMBT1, passed through the GEANT4 simulation of the ATLAS detector. The detector simulation accounts for energy losses of the particles in material upstream of the calorimeter, for charged particles that bend in the magnetic field and get swept out of the calorimeter acceptance, and for the calorimeter response and resolution. Before unfolding each ΣE_T distribution, the MC is reweighted by a fit to the ratio of the data to the MC detector-level ΣE_T distribution, so that the ΣE_T distribution matches that seen in data. The MC significantly underestimates the ΣE_T in the forward region, as seen in figure 2, where the detector-level ΣE_T distribution in the region $4.0 < |\eta| < 4.8$ is shown for both data and MC, before and after reweighting, for both the minimum bias and dijet selections.

The unfolding matrix associates the ΣE_T formed from clusters with the ΣE_T formed from generator-level particles. Events that pass the detector-level but not the particle-level selection criteria and vice versa are also accounted for in the correction procedure. The prior distribution of the particle-level ΣE_T is initially taken from PYTHIA 6 AMBT1 (reweighted to data) and the unfolding procedure is iterated twice, with the prior distribution replaced by the unfolded distribution after each iteration. A stable result is achieved after two iterations.

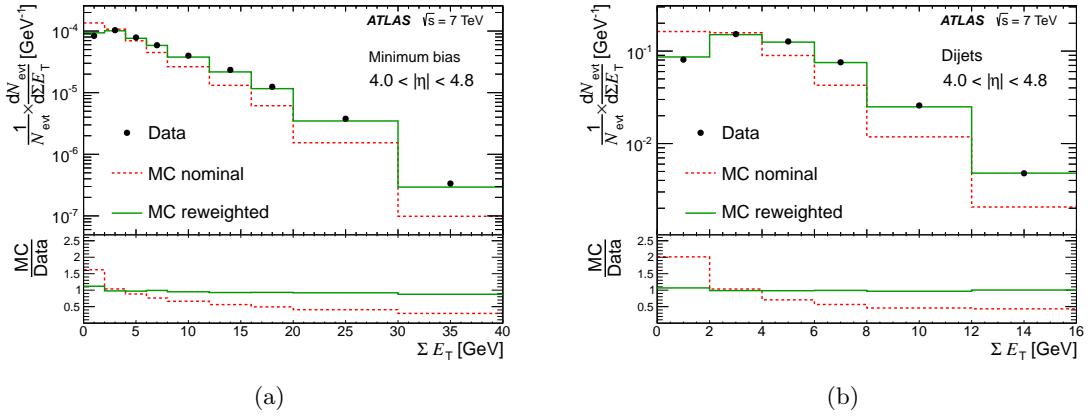

Figure 2. The detector-level ΣE_T distribution in the region $4.0 < |\eta| < 4.8$ for data compared to the nominal detector-level PYTHIA 6 AMBT1 prediction and the reweighted detector-level PYTHIA 6 AMBT1 prediction in (a) the minimum bias events and (b) the dijet events.

8 Systematic uncertainties

The dominant systematic uncertainties arise from three sources: (1) the accuracy with which the MC simulates the energy response of the calorimeters to low energy particles, (2) the knowledge of the amount of material upstream of the calorimeters and (3) the MC generator model dependence in the unfolding. In the dijet analysis an additional uncertainty arises from the accuracy with which the MC simulates the jet energy scale. These sources are discussed in the following sub-sections. In each case the uncertainty on the unfolded data is obtained by shifting the MC by $\pm 1\sigma$ for the source in question and comparing with the nominal unfolded data. In order to give information about the correlations of the systematic uncertainties between bins and between the different distributions in this paper, each source is split into different components. These systematic uncertainties are summarized in tabular form in appendix A.

The following additional potential sources of systematic uncertainty are found to be negligible: energy resolution, multiple proton-proton interactions, contributions from noise and beam-induced backgrounds, simulation of the primary vertex position, simulation of the trigger selection, and simulation of the position of the forward calorimeter.

8.1 Calorimeter energy response

The systematic uncertainty on the calorimeter energy response is determined separately for electromagnetic and hadronic particles. An average is then obtained, using the PYTHIA 6 AMBT1 prediction of the relative contributions to the ΣE_T by different particle types. For electromagnetic particles the systematic error comes from uncertainties on the extraction of the energy scale from fits to the $m_{\gamma\gamma}$ distributions in $\pi^0 \rightarrow \gamma\gamma$ candidates. These are obtained from variations in the fit range, the background shape, the criteria for matching reconstructed photons to generator-level photons in the production of the signal template, variations in the simulation of the calorimeter resolution, and consistency with a similar

analysis using tighter kinematic and photon identification cuts. The total uncertainty depends on the $|\eta|$ region and is generally at the level of 2–4%, but increases up to 15% in the regions where different calorimeter sub-systems overlap.

The uncertainty on the energy response for hadronic particles in the central region, where there is good coverage from the inner tracking detector, is obtained from studies of the ratio of the calorimeter energy measurement to the inner detector track momentum measurement, for isolated charged pions [43]. The uncertainty is obtained by taking the difference between data and MC in p and $|\eta|$ bins and is found to be 3.5% for $|\eta| < 0.8$ and 5% for $0.8 < |\eta| < 2.4$. In the forward region the energy response uncertainty for hadrons is taken from the difference between the MC and data in test-beam studies of charged pions [44]. This leads to a one-sided uncertainty for hadrons relative to electromagnetic particles of +5% in the region $2.5 < |\eta| < 3.2$ and +9% in the forward calorimeter ($|\eta| > 3.2$).

The only component of the systematic uncertainty on the energy response assumed to be correlated between $|\eta|$ bins is that of the forward calorimeter (determined from test-beam results), which affects the bins $3.2 < |\eta| < 4.0$ and $4.0 < |\eta| < 4.8$. The systematic uncertainties from the $\pi^0 \rightarrow \gamma\gamma$ fits are assumed to be uncorrelated as the $m_{\gamma\gamma}$ shapes are rather different in the different $|\eta|$ regions, resulting in different possible systematic shifts. Similarly, the difference between data and MC for the ratio of calorimeter energy to inner detector track momentum does not show systematic shifts in one direction and is assumed to be uncorrelated.

Appendix A gives both the uncorrelated and correlated uncertainties in each bin of each distribution. The former vary between 2.4% and 5.4% for the E_T^{density} in the minimum bias data, depending on the $|\eta|$ region. The largest uncertainty is in the region $0.8 < |\eta| < 1.6$, which contains the region of overlap between the barrel and endcap electromagnetic calorimeters ($1.375 < |\eta| < 1.475$). The correlated source is about –6% for the two highest $|\eta|$ bins in the minimum bias data and about –8% in the dijet data. Note that a positive uncertainty on the energy scale in the MC leads to a negative uncertainty on the corrected result in the data. The uncertainty is higher in the dijet data, due to a larger contribution from events where the detector-level jets pass the selection criteria but the generator-level jets do not. Their ΣE_T distribution is taken from the MC so a shift in the energy scale leads to an additional bias in the corrected result.

8.2 Material description

The amount of material upstream of the calorimeters affects the ΣE_T distributions because particles can interact and lose some of their energy before reaching the calorimeter. It is therefore important to have a realistic description of the material in the MC simulation used to perform the detector corrections.

In order to assess the systematic uncertainty arising from possible discrepancies in the material description, detector corrections are recalculated using a special PYTHIA 6 AMBT1 sample with additional material. The sample is based on a similar one described in section 3 of ref. [45], but with additional material introduced in the forward region. The results are compared to the nominal unfolded data and the difference is taken as a

symmetric systematic uncertainty to account for the possibility of the MC simulation either underestimating or overestimating the amount of material.

In order to understand the correlations between the uncertainties in different $|\eta|$ bins, the additional material is split into three components: (1) extra material upstream of the barrel calorimeter, (2) an increase in material density in the barrel-endcap overlap region and (3) additional material in the inner detector, the inner detector services and the forward region, as well as an increase in the material density in some detector volumes in the forward region. The systematic uncertainties arising from components (1) and (2) are assumed to be correlated between $|\eta|$ bins, whereas the uncertainty arising from component (3) is assumed to be uncorrelated, due to the fine structure of these detectors with respect to the wide bins used in this analysis.

Source (1) affects only the first two $|\eta|$ bins, at the level of about 3% in the minimum bias data and 1.3–2.5% in the dijet data. The uncertainty is generally smaller in the dijet data as the particles in these events tend to have larger momenta. Source (2) affects only the second and third bins and is less than 1%. Source (3) affects all $|\eta|$ bins and ranges between 0.23% and 5.5%, with the largest uncertainty in the region $1.6 < |\eta| < 2.4$, where there is a large amount of material associated with the inner detector.

8.3 Physics model dependence

The MC model used to correct the data can affect the results as a realistic description of particle kinematics is needed. The model dependence is minimized by first reweighting the detector-level MC to the data and then by iterating the unfolding, using the unfolded data as the new prior distribution after each iteration. This reduces the dependence on the ΣE_T spectrum itself; however, other kinematic distributions can also affect the unfolding. One important variable is the E_T of the individual particles, as the calorimeter response to a particle is energy dependent. The dependence on the model is investigated by performing the unfolding with other MC models. The following MC models and tunes are considered: PYTHIA 6 AMBT1 (nominal), PYTHIA 6 DW, PYTHIA 6 Perugia0, PYTHIA 8 4C and *Herwig*++ UE7–2. Details of these tunes are given in table 1. The MC model used to assess the systematic uncertainty is chosen to ensure a reasonable spread in the particle kinematics with respect to the reference PYTHIA 6 AMBT1 model. Figure 3 shows distributions of $\frac{1}{E_T^{\text{tot}}} \times \frac{dE_T^{\text{tot}}}{d|E_T|}$, where E_T^{tot} is the sum over events of the detector-level ΣE_T , and E_T is the detector-level cluster transverse energy. These distributions show the relative contribution to the ΣE_T from clusters with a given $|E_T|$. $|E_T|$ is plotted instead of E_T since the former leads to a cancellation in the contribution from noise. Figure 3(a) shows the distribution in minimum bias events for the region $3.2 < |\eta| < 4.0$. This region is shown as it has significant differences between data and MC. The contribution to the ΣE_T from high E_T clusters is smaller in data than in PYTHIA 6 AMBT1. The model with the largest deviations from PYTHIA 6 AMBT1 is *Herwig*++ UE7–2, indicating that this model can be used to assess possible biases in the unfolding due to this effect. It should be noted that at high $|E_T|$ *Herwig*++ UE7–2 lies above PYTHIA 6 AMBT1 while the data lie below it, but the final systematic uncertainty is symmetrized. The same distribution is shown in figure 3(b) for the sub-sample of events with $\Sigma E_T > 15$ GeV. Again, the data have a softer cluster

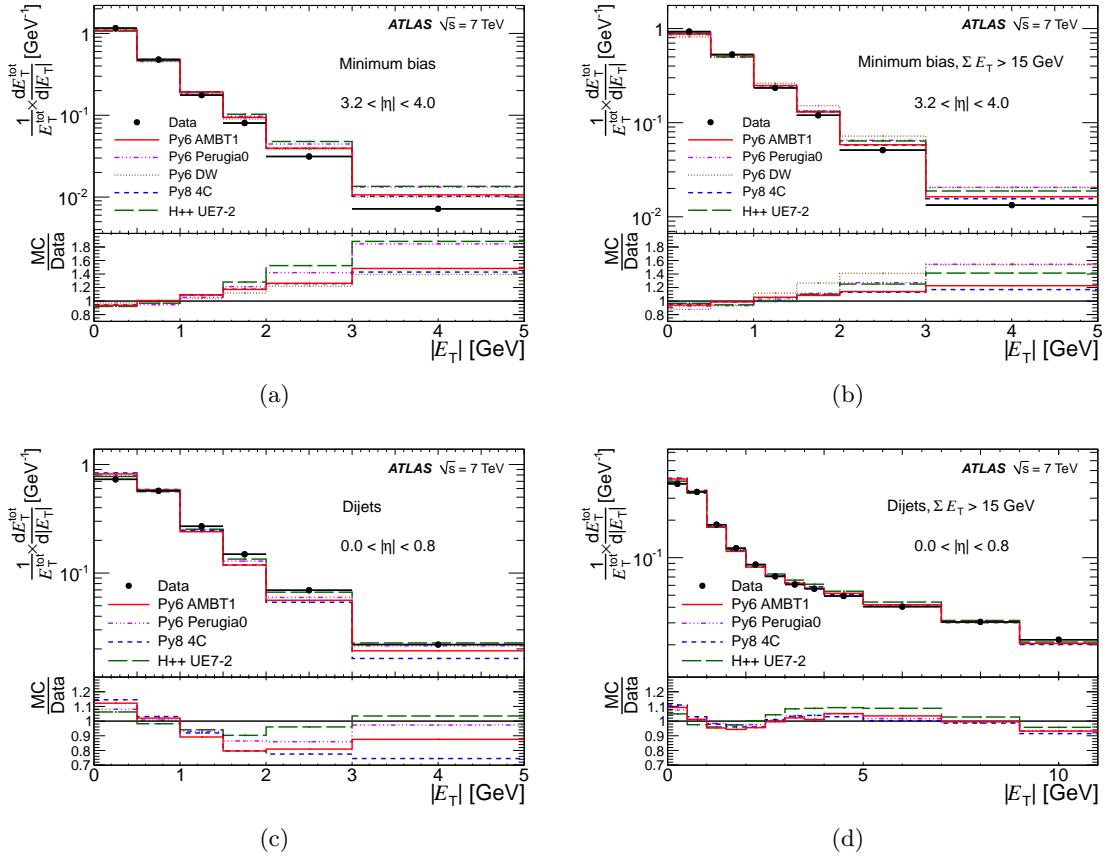

Figure 3. Distribution of $\frac{1}{E_T^{\text{tot}}} \times \frac{dE_T^{\text{tot}}}{d|E_T|}$, where E_T^{tot} is the sum over events of the detector-level ΣE_T , and E_T is the detector-level cluster transverse energy (a) in minimum bias events in the region $3.2 < |\eta| < 4.0$; (b) as in (a) but for events with $\Sigma E_T > 15$ GeV; (c) in dijet events in the region $0.0 < |\eta| < 0.8$; (d) as in (c) but for events with $\Sigma E_T > 15$ GeV. The data are compared to various MC predictions.

$|E_T|$ distribution. Here PYTHIA 6 DW shows the largest deviations from PYTHIA 6 AMBT1. Since unfolding with PYTHIA 6 DW results in a larger shift in the corrected data than unfolding with **Herwig++** UE7-2, the former is used to assess the systematic uncertainty in the minimum bias events.

Figure 3(c) shows the same distribution in dijet events; the most central region is shown as the differences between data and MC are largest in this region. This time the data distribution is harder than PYTHIA 6 AMBT1. Again **Herwig++** UE7-2 has the largest deviations. Figure 3(d) shows the same distribution for events with $\Sigma E_T > 15$ GeV; all the models agree well with the data, but **Herwig++** UE7-2 has the largest deviations. For the dijet selection **Herwig++** UE7-2 is therefore used to assess the systematic uncertainty.

For both the minimum bias and dijet analyses, this systematic uncertainty is symmetrized and treated as correlated between $|\eta|$ bins (although not correlated between the two analyses). The uncertainties on the E_T^{density} range from 2–4% for the minimum bias

data and are 2% or less for the dijet data.

8.4 Jet energy scale

In the dijet selection, events are required to contain at least two jets with $E_T > 20$ GeV. It is possible that events that satisfy the detector-level criteria do not satisfy the criteria at the particle-level, and vice versa. This is accounted for in the correction procedure, but if there are differences in the jet energy scale between data and MC simulation this could result in a bias in the correction procedure. The uncertainty on the jet energy scale is described in ref. [46]. The corresponding uncertainty on the E_T^{density} is at the level of 1.6% in the most central bin and decreases to 0.13% in the most forward bin. It is treated as correlated between $|\eta|$ bins. For the ΣE_T distributions this source of uncertainty is negligible and therefore neglected in the region $|\eta| > 2.4$.

9 Results

9.1 Nominal Results

The unfolded E_T^{density} distributions are shown in figure 4 for both the minimum bias and the dijet selections. The filled bands indicate the systematic and statistical uncertainties on the data, added in quadrature. In all bins the systematic uncertainty is significantly larger than the statistical uncertainty. The E_T^{density} distribution in the minimum bias data dips in the central region. Since the relative fraction of low momentum particles is higher in the central region than in the forward region, fewer central particles pass the selection criteria described in section 2, hence reducing the ΣE_T in the central region. The dip in the central region is less prominent in the dijet data; this feature is discussed below.

Figure 5 shows the ratio of the E_T^{density} in the dijet transverse region to the E_T^{density} in minimum bias events. The correlations between the systematic uncertainties for the dijet and minimum bias distributions are taken into account. All systematic uncertainties but the physics model dependence and jet energy scale are taken as correlated between the two. The E_T^{density} in the transverse region for the dijet selection is larger than the E_T^{density} in the minimum bias data. This increase is expected, due primarily to the presence of a hard scatter, which will bias the selected events away from peripheral proton scatters and towards small impact parameter (“head-on”) proton-proton interactions. This means that more parton-parton interactions are likely to occur in the underlying event in the dijet data than in the collisions with a larger impact parameter that characterize the events in the minimum bias dataset.

The unfolded data are compared to various MC models. In the minimum bias sample the E_T^{density} distribution in figure 4(a) is well described by PYTHIA 6 AMBT1 in the central region. This is expected as this tune was prepared with ATLAS 7 TeV minimum bias data in the region $|\eta| < 2.5$ [3]. At higher $|\eta|$ values, however, the E_T^{density} is underestimated and is approximately 25% too low in the highest $|\eta|$ bin. The PYTHIA 6 AUET2B:CTEQ6L1 prediction is very similar to that from PYTHIA 6 AMBT1, with slightly more energy in the central region and less in the forward region, meaning that the description of the $|\eta|$ dependence is even

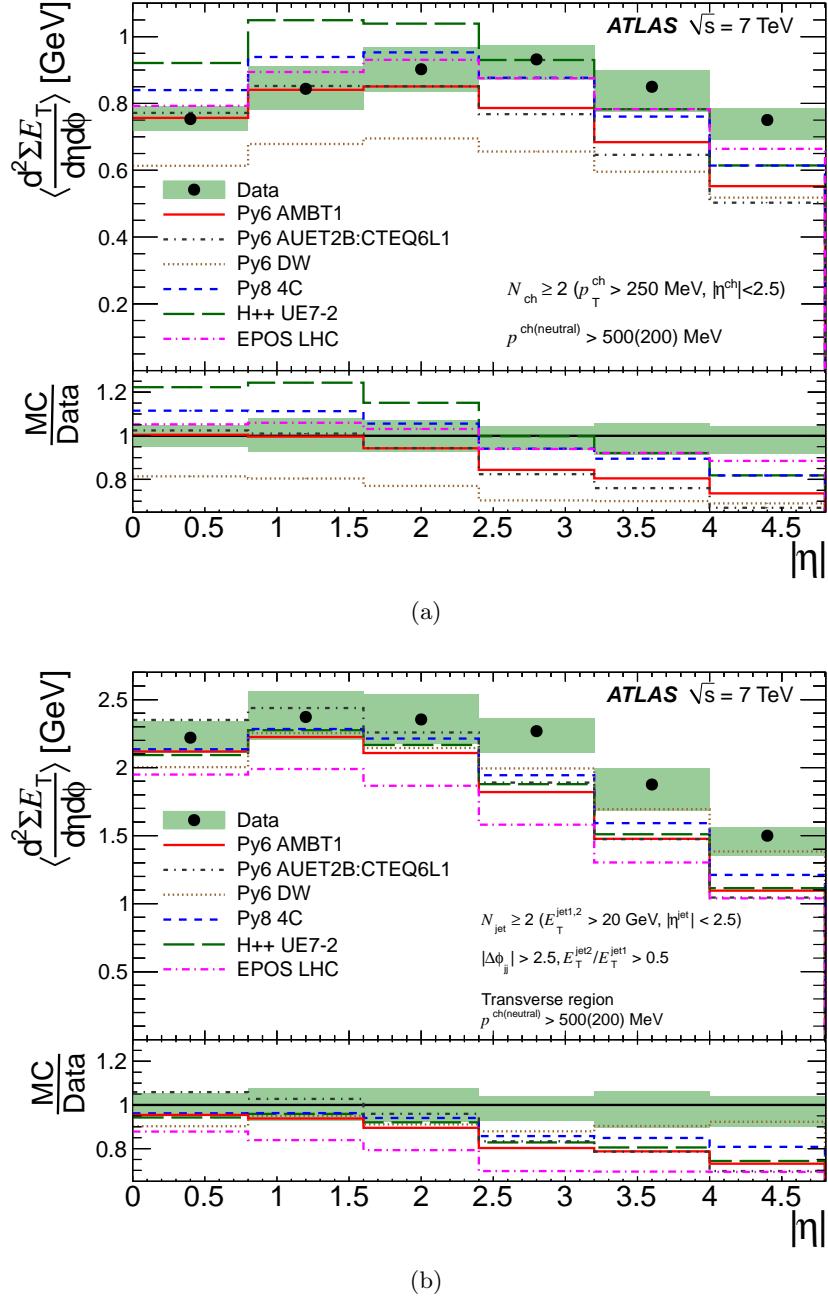

Figure 4. Unfolded E_T^{density} distribution compared to various MC models and tunes for (a) the minimum bias selection and (b) the dijet selection in the transverse region. The filled band represents the total uncertainty on the unfolded data. N_{ch} refers to the number of charged particles in the event, and p_T^{ch} and η^{ch} are, respectively, the p_T and η of those particles. N_{jet} refers to the number of jets, $E_T^{\text{jet}1(2)}$ is the E_T of the (sub-)leading jet, η^{jet} is the jet pseudorapidity, and $\Delta\phi_{jj}$ is the azimuthal angle difference between the two leading jets. $p_T^{\text{ch(neutral)}}$ refers to the momentum of the charged(neutral) particles used in the ΣE_T calculation.

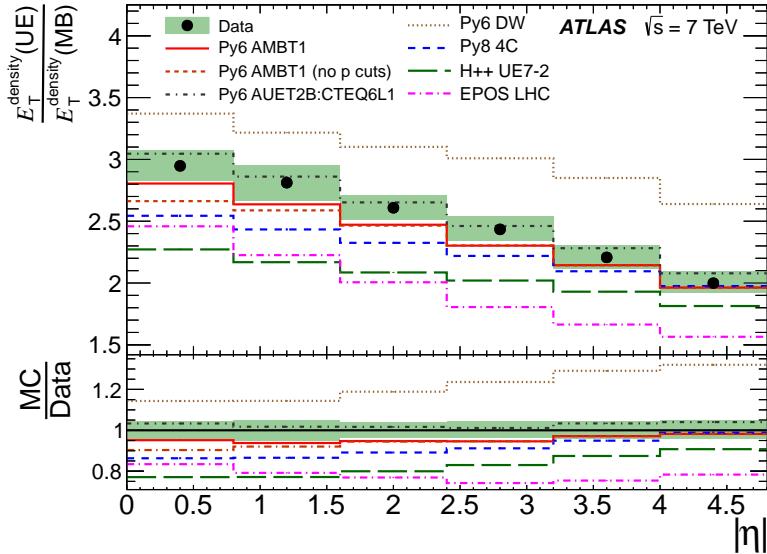

Figure 5. Unfolded E_T^{density} distribution in the dijet data transverse region divided by that in the minimum bias data, compared to various MC models and tunes. The filled band represents the total uncertainty on the unfolded data.

worse. PYTHIA 6 DW underestimates the E_T^{density} in all $|\eta|$ bins. Despite this it provides an improved description of the $|\eta|$ dependence of the E_T^{density} . PYTHIA 8 4C overestimates the E_T^{density} in the central region. The agreement improves in the region $1.6 < |\eta| < 3.2$, but in the higher $|\eta|$ bins the E_T^{density} is underestimated. Herwig++ UE7-2 overestimates the E_T^{density} in the central region, describes the data well in the region $2.4 < |\eta| < 3.2$, and undershoots the data at higher $|\eta|$. The EPOS LHC prediction provides the best description over the entire $|\eta|$ region, although it does fall slightly too fast with $|\eta|$. It should be noted that, with the exception of EPOS LHC and PYTHIA 6 DW, while some models and tunes appear to agree better in some regions than others, this is generally due to differences in the total level of particle production. The overall pattern remains the same: the E_T^{density} in the forward region is too low relative to the central region.

In the dijet selection in figure 4(b), all of the MC models and tunes perform reasonably well in the central region, apart from EPOS LHC which underestimates the E_T^{density} in all $|\eta|$ bins. PYTHIA 6 AUET2B:CTEQ6L1 slightly overestimates the energy in the most central bins, and all the other predictions are slightly too low. As was the case in the minimum bias analysis, the E_T^{density} in the forward region is underestimated. PYTHIA 8 4C is approximately 20% too low in the most forward bin, while PYTHIA 6 AMBT1, Herwig++ UE7-2 and PYTHIA 6 AUET2B:CTEQ6L1 are 25–30% too low. PYTHIA 6 DW provides the best description of the $|\eta|$ dependence, although the overall amount of energy is too low.

The fall-off with $|\eta|$ of the ratio of the E_T^{density} in dijet and minimum bias events seen in figure 5 is reproduced by the models, with PYTHIA 6 AMBT1 and AUET2B:CTEQ6L1 describing the data the best. The reduction in the ratio with $|\eta|$ is partly due to the momentum cuts on the particles included in the ΣE_T calculation. In the dijet data, the particles tend to

have larger momenta and so fewer are removed from the ΣE_T calculation. According to PYTHIA 6 AMBT1, the momentum cuts remove 25(18)% of the E_T^{density} in the most central bin and a negligible amount in the most forward bin for the minimum bias (dijet) selections. The PYTHIA 6 AMBT1 (no p cuts) curve in figure 5, shows the ratio when the momentum cuts on the particles contributing to the ΣE_T have been removed. There is still a residual decrease with $|\eta|$ which may be due to a contribution to the underlying event in the central region coming from particles associated with the hard scatter.

The unfolded ΣE_T distributions are shown in figures 6 and 7 for the minimum bias and dijet selections, respectively. The distribution peaks at higher values of ΣE_T in the forward region due to the particle momentum cuts discussed above. In the region $|\eta| < 3.2$ the distribution is broader than in the forward region, with more events populating the high ΣE_T tails. There is therefore more event-by-event variation in the ΣE_T in the central part of the detector. These features are reproduced by the MC predictions. PYTHIA 6 AMBT1 provides the best description of the ΣE_T shape in the central region for the minimum bias data. For the dijet data, most of the tunes do a reasonable job, although PYTHIA 8 4C and EPOS LHC underestimate the high ΣE_T tails. As with the E_T^{density} distributions, the ΣE_T in the forward region is underestimated for all but the dijet PYTHIA 6 DW prediction.

In summary, all of the MCs underestimate the amount of energy in the forward region relative to the central region, in both the minimum bias data and the underlying event, with the exception of PYTHIA 6 DW which provides a reasonable description of the dijet data, although the prediction is approximately one standard deviation below the central values measured in the data in all $|\eta|$ bins. EPOS LHC provides the best overall description of the minimum bias data. PYTHIA 6 AMBT1 provides the best description in the most central region ($|\eta| < 1.6$), while at higher $|\eta|$ values PYTHIA 8 4C and Herwig++ UE7-2 reflect the data more accurately. In the dijet analysis, all the MCs provide a reasonable description in the central region, apart from EPOS LHC.

9.2 Variation in diffractive contributions

In order to investigate the sensitivity of the E_T^{density} to the fraction of diffractive events, figure 8 compares the unfolded E_T^{density} distribution in the minimum bias data to PYTHIA 8 4C with the nominal diffractive cross-sections (50.9 mb, 12.4 mb and 8.1 mb for non-diffractive, single-diffractive and double-diffractive processes, respectively) and to samples where the diffractive cross-sections have been doubled or halved, with the non-diffractive cross-section held constant. This is achieved by combining the separate MC samples for the different processes with adjusted weights, rather than by changing the relevant parameters when generating the samples. Diffractive processes tend to have less particle production than non-diffractive processes. As expected, increasing the diffractive contribution decreases the E_T^{density} . However, the shape of the E_T^{density} distribution is not significantly affected.

9.3 Variation in parton distribution functions

The overall energy as well as its $|\eta|$ dependence are affected by the PDFs used as input to the MC model. In order to investigate the dependence on the PDFs, comparisons are made

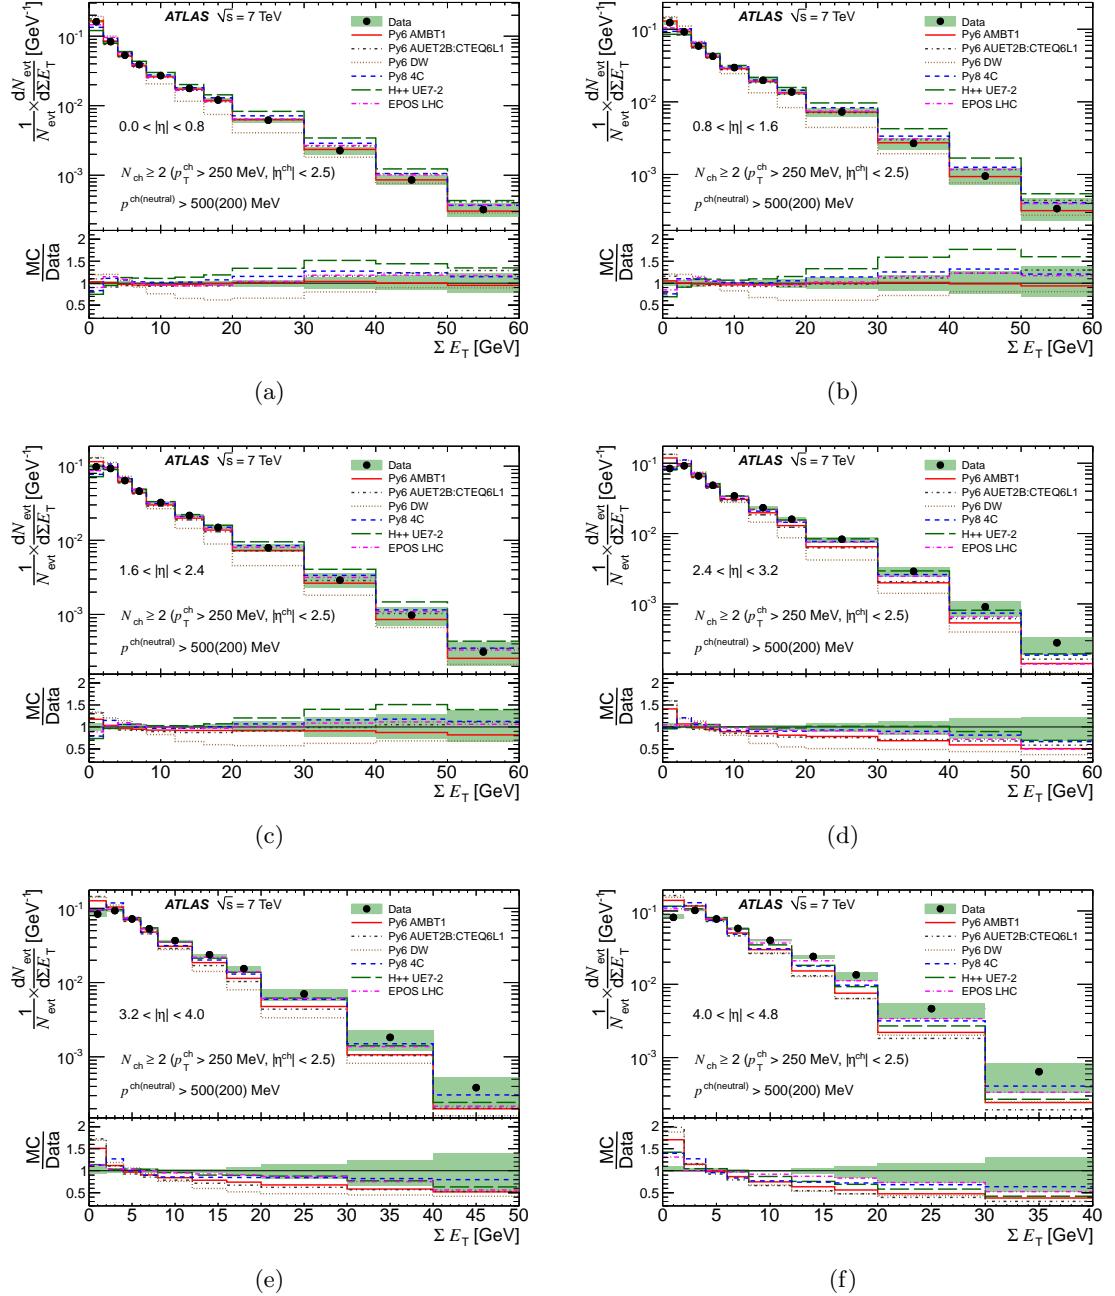

Figure 6. Unfolded ΣE_T distributions compared to various MC models and tunes for the minimum bias selection in the following $|\eta|$ regions: (a) $0.0 < |\eta| < 0.8$, (b) $0.8 < |\eta| < 1.6$, (c) $1.6 < |\eta| < 2.4$, (d) $2.4 < |\eta| < 3.2$, (e) $3.2 < |\eta| < 4.0$ and (f) $4.0 < |\eta| < 4.8$. The filled band in each plot represents the total uncertainty on the unfolded data. N_{ch} refers to the number of charged particles in the event, and p_T^{ch} and η^{ch} are, respectively, the p_T and η of those particles. $p^{ch(neutral)}$ refers to the momentum of the charged(neutral) particles used in the ΣE_T calculation.

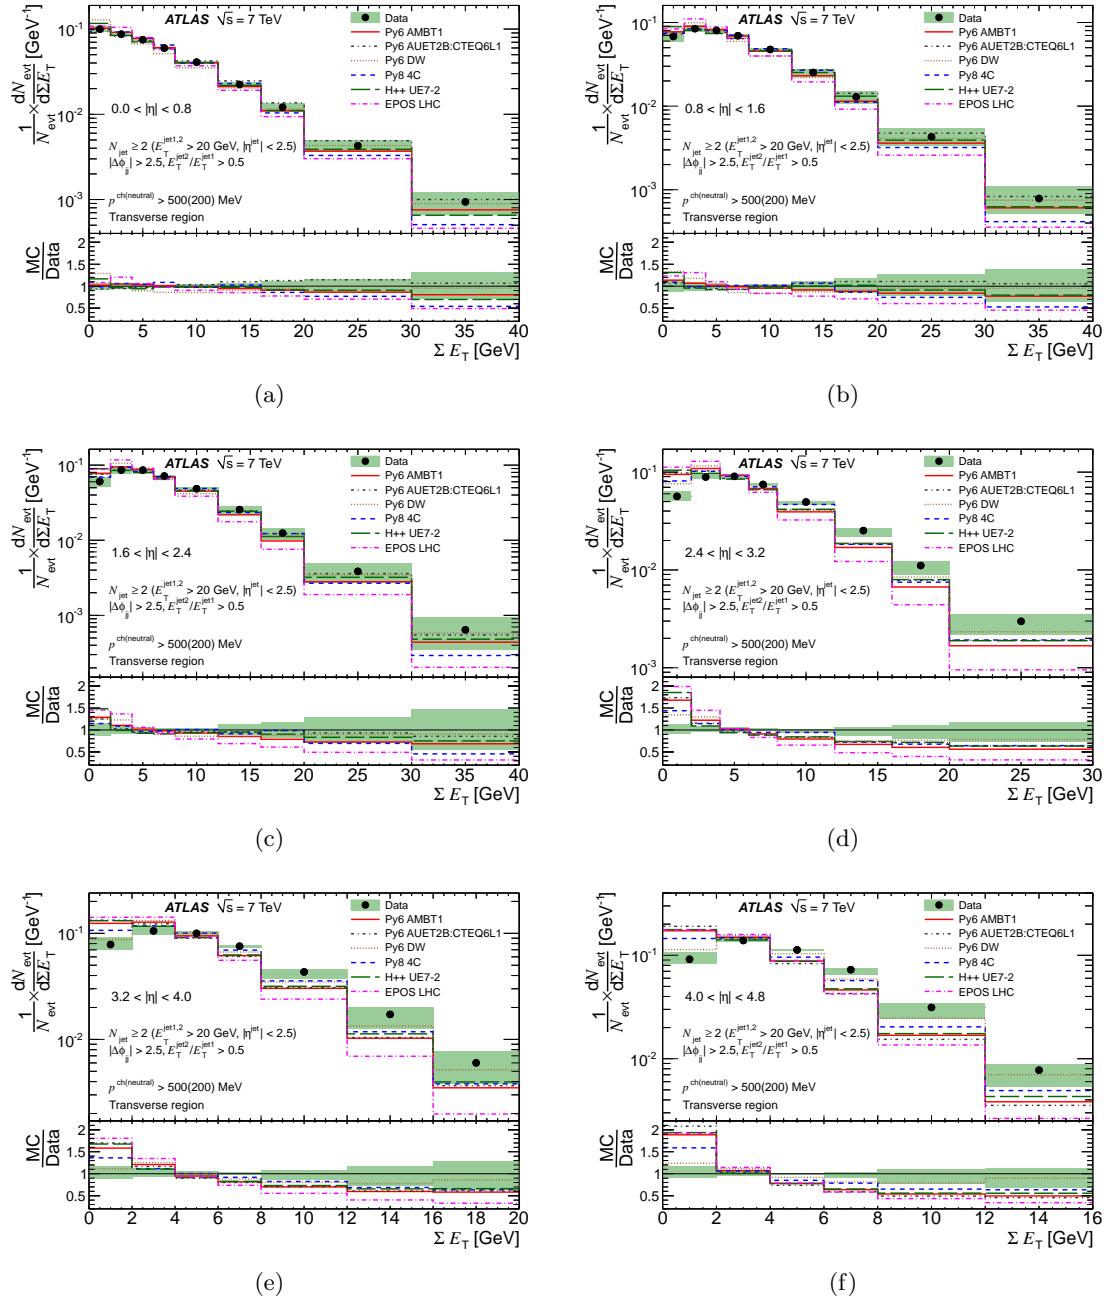

Figure 7. Unfolded ΣE_T distributions compared to various MC models and tunes for the dijet selection in the transverse region in the following $|\eta|$ regions: (a) $0.0 < |\eta| < 0.8$, (b) $0.8 < |\eta| < 1.6$, (c) $1.6 < |\eta| < 2.4$, (d) $2.4 < |\eta| < 3.2$, (e) $3.2 < |\eta| < 4.0$ and (f) $4.0 < |\eta| < 4.8$. The filled band in each plot represents the total uncertainty on the unfolded data. N_{jet} refers to the number of jets, $E_T^{\text{jet}1(2)}$ is the E_T of the (sub-)leading jet, η^{jet} is the jet pseudorapidity, and $\Delta\phi_{jj}$ is the azimuthal angle difference between the two leading jets. $p_{\text{ch(neutral)}}$ refers to the momentum of the charged(neutral) particles used in the ΣE_T calculation.

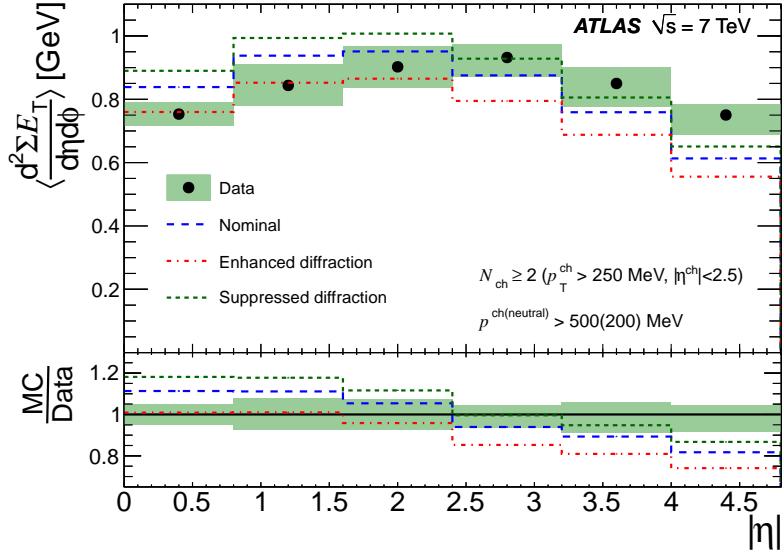

Figure 8. Final unfolded E_T^{density} distribution for the minimum bias selection compared to PYTHIA 8 4C with the nominal diffractive cross-sections, as well as enhanced and suppressed diffractive cross-sections, as described in the text. The filled band represents the total uncertainty on the unfolded data. N_{ch} refers to the number of charged particles in the event, and p_T^{ch} and η^{ch} are, respectively, the p_T and η of those particles. $p_T^{\text{ch(neutral)}}$ refers to the momentum of the charged(neutral) particles used in the ΣE_T calculation.

between the data and the PYTHIA 8 A2 family of tunes, which use different input PDFs [33], with the following variations:

1. Tune A2:CTEQ6L1.
2. The A2:CTEQ6L1 tune parameters, but with the MSTW2008 LO PDFs.
3. Tune A2:MSTW2008LO.
4. Tune A2:CTEQ6L1 where the E_T^{density} has been scaled by 0.93(0.96) for the minimum bias (dijet) selection so that it matches A2:MSTW2008LO in the most central bin.

These comparisons are shown in figure 9. The first thing to note is that moving from the CTEQ 6L1 to the MSTW2008 LO PDFs (and keeping all tune parameters the same) decreases the amount of energy in the central region, but increases it in the forward region, presumably due to the increase in both the high- x and low- x gluon PDF with respect to the mid- x region, where x is the proton momentum fraction carried by the gluon. When the parameters are tuned to data in the central region, the energy increases for the minimum bias prediction. If the E_T^{density} obtained using A2:CTEQ6L1 is scaled down to match A2:MSTW2008LO in the most central bin, it is clear that the latter provides a better description of the data in the forward region, with the underestimation in the most forward bin improving from about 30% to 15%.

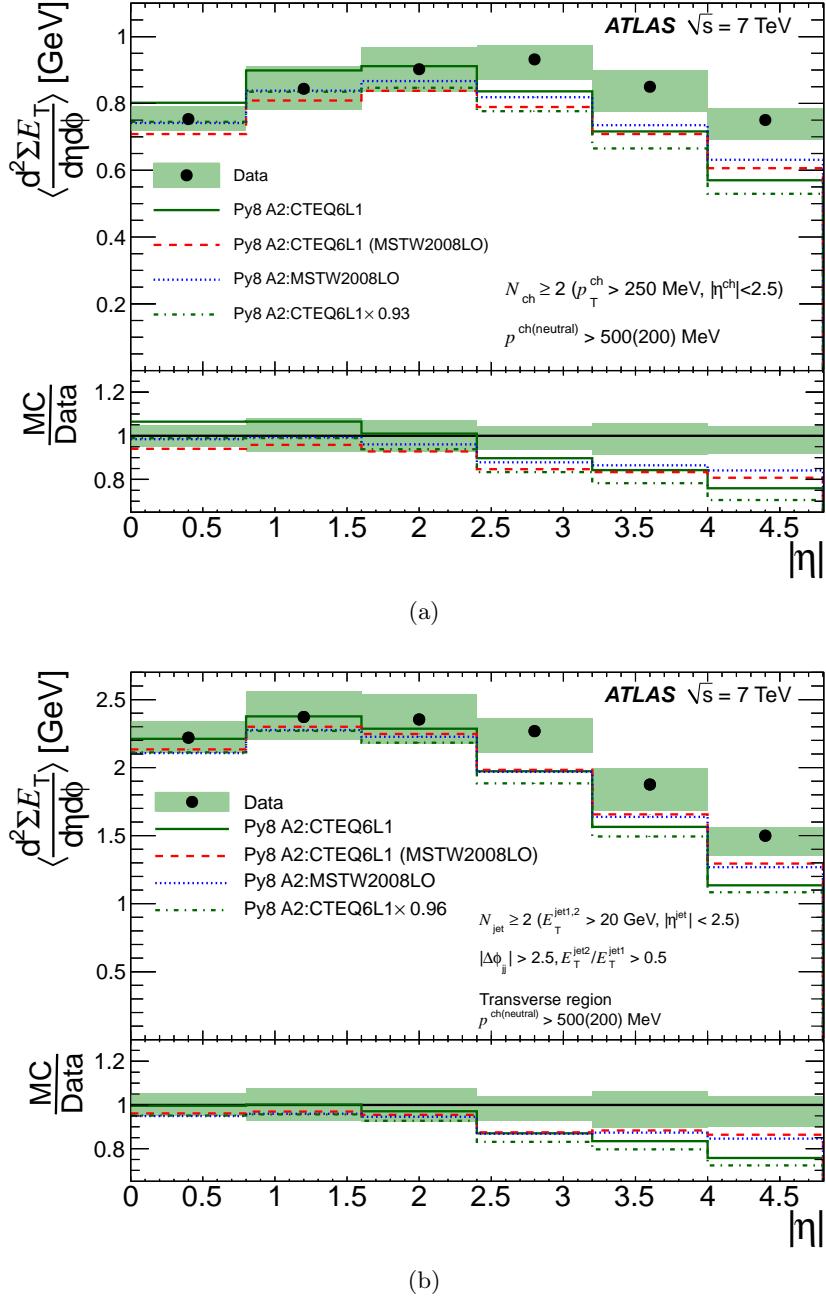

Figure 9. Final unfolded E_T^{density} distribution compared to PYTHIA 8 with variations of the PDFs used, as discussed in the text for (a) the minimum bias selection and (b) the dijet selection. The filled band represents the total uncertainty on the unfolded data. N_{ch} refers to the number of charged particles in the event, and p_T^{ch} and η^{ch} are, respectively, the p_T and η of those particles. N_{jet} refers to the number of jets, $E_T^{\text{jet}1(2)}$ is the E_T of the (sub-)leading jet, η^{jet} is the jet pseudorapidity, and $\Delta\phi_{jj}$ is the azimuthal angle difference between the two leading jets. $p^{\text{ch(neutral)}}$ refers to the momentum of the charged(neutral) particles used in the ΣE_T calculation.

10 Conclusions

Measurements of the E_T^{density} and the ΣE_T distributions as functions of $|\eta|$ have been presented for two event classes: those requiring the presence of particles with a low transverse momentum (minimum bias) and those requiring particles with a significant transverse momentum (dijets), using proton-proton collision data at $\sqrt{s} = 7$ TeV recorded by the ATLAS detector. In the dijet selection the distributions are measured in the region transverse in ϕ to the hard scatter, in order to probe the particle production from the underlying event. The measurements are performed in the region $|\eta| < 4.8$ for charged particles with $p > 500$ MeV and neutral particles with $p > 200$ MeV, and are the first to utilize the entire acceptance of the ATLAS calorimeters to probe the overall properties of inclusive proton-proton collisions, as well as the underlying event. The distributions are compared to various MC models and tunes. In general all MC predictions are found to underestimate the amount of energy in the forward region relative to the central region by 20–30%, with the exception of the PYTHIA 6 DW tune and EPOS LHC for the minimum bias data, although PYTHIA 6 DW underpredicts the overall energy by 20–30%. For the PYTHIA 8 A2 tune series, this is improved if the MSTW2008 LO PDFs are used instead of the CTEQ 6L1 PDFs.

A Tabulated results and uncertainties

The unfolded data are presented in tabular form in this appendix for the E_T^{density} and the six ΣE_T distributions, for both the minimum bias and dijet selections. Tables 3, 4 and 5 give the unfolded data and systematic uncertainties for the E_T^{density} for the minimum bias selection, the dijet selection, and the ratio between them, respectively. Tables 6–11 give the unfolded data and systematic uncertainties for the ΣE_T distributions for the minimum bias selection and tables 12–17 give the corresponding information for the dijet analysis. In each case, the breakdown of the systematic uncertainties by source is also given. Each systematic source is described in section 8. The uncorrelated calorimeter energy scale systematic is denoted as $E_1^{a,b,c,d,e,f}$ for each of the six $|\eta|$ regions, respectively. The correlated calorimeter energy scale systematic is denoted as E_2 . The two correlated material systematic sources are denoted as M_1 and M_2 and the uncorrelated source is denoted as $M_3^{a,b,c,d,e,f}$ for the six $|\eta|$ regions. All the above sources are correlated between the minimum bias data and the dijet data and therefore have the same symbol.

The physics model systematic uncertainty on the minimum bias and dijet results, and on their ratio, are denoted as, P_1 , P_2 and P , respectively. The jet energy scale systematic uncertainty is denoted as J . The physics model and jet energy scale systematic sources are uncorrelated between the minimum bias and dijet data. For the ΣE_T distributions J is negligible and therefore neglected in the region $|\eta| > 2.4$.

The correlations between bins of a given distribution are indicated by the sign of the uncertainty. For example, in table 6 the uncertainty E_1^a is \pm in the first three bins and \mp in the remaining bins. This means that the first three bins are correlated with each other and anti-correlated with the remaining bins (a downward shift in the ΣE_T will shift the low ΣE_T bins up and the high ΣE_T bins down). Since the individual sources within a given distribution are uncorrelated, the relationship between \pm and \mp between sources is not relevant to the calculation of the total error in a given bin.

The uncertainties are given to two significant figures or a precision of 0.01%, whichever is smaller. In cases where the + and – uncertainty have a different precision the lowest precision is chosen for both. In cases where the uncertainty is not applicable, this is indicated with a dash.

¹²⁴ Institute of Physics, Academy of Sciences of the Czech Republic, Praha, Czech Republic
¹²⁵ Faculty of Mathematics and Physics, Charles University in Prague, Praha, Czech Republic
¹²⁶ Czech Technical University in Prague, Praha, Czech Republic
¹²⁷ State Research Center Institute for High Energy Physics, Protvino, Russia
¹²⁸ Particle Physics Department, Rutherford Appleton Laboratory, Didcot, United Kingdom
¹²⁹ Physics Department, University of Regina, Regina SK, Canada
¹³⁰ Ritsumeikan University, Kusatsu, Shiga, Japan
¹³¹ ^(a)INFN Sezione di Roma I; ^(b)Dipartimento di Fisica, Università La Sapienza, Roma, Italy
¹³² ^(a)INFN Sezione di Roma Tor Vergata; ^(b)Dipartimento di Fisica, Università di Roma Tor Vergata, Roma, Italy
¹³³ ^(a)INFN Sezione di Roma Tre; ^(b)Dipartimento di Fisica, Università Roma Tre, Roma, Italy
¹³⁴ ^(a)Faculté des Sciences Ain Chock, Réseau Universitaire de Physique des Hautes Energies - Université Hassan II, Casablanca; ^(b)Centre National de l'Energie des Sciences Techniques Nucleaires, Rabat; ^(c)Faculté des Sciences Semlalia, Université Cadi Ayyad, LPHEA-Marrakech; ^(d)Faculté des Sciences, Université Mohamed Premier and LPTPM, Oujda; ^(e)Faculté des sciences, Université Mohammed V-Agdal, Rabat, Morocco
¹³⁵ DSM/IRFU (Institut de Recherches sur les Lois Fondamentales de l'Univers), CEA Saclay (Commissariat a l'Energie Atomique), Gif-sur-Yvette, France
¹³⁶ Santa Cruz Institute for Particle Physics, University of California Santa Cruz, Santa Cruz CA, United States of America
¹³⁷ Department of Physics, University of Washington, Seattle WA, United States of America
¹³⁸ Department of Physics and Astronomy, University of Sheffield, Sheffield, United Kingdom

- ¹³⁹ Department of Physics, Shinshu University, Nagano, Japan
¹⁴⁰ Fachbereich Physik, Universität Siegen, Siegen, Germany
¹⁴¹ Department of Physics, Simon Fraser University, Burnaby BC, Canada
¹⁴² SLAC National Accelerator Laboratory, Stanford CA, United States of America
¹⁴³ ^(a)Faculty of Mathematics, Physics & Informatics, Comenius University, Bratislava;
^(b)Department of Subnuclear Physics, Institute of Experimental Physics of the Slovak
Academy of Sciences, Kosice, Slovak Republic
¹⁴⁴ ^(a)Department of Physics, University of Johannesburg, Johannesburg; ^(b)School of
Physics, University of the Witwatersrand, Johannesburg, South Africa
¹⁴⁵ ^(a)Department of Physics, Stockholm University; ^(b)The Oskar Klein Centre,
Stockholm, Sweden
¹⁴⁶ Physics Department, Royal Institute of Technology, Stockholm, Sweden
¹⁴⁷ Departments of Physics & Astronomy and Chemistry, Stony Brook University, Stony
Brook NY, United States of America
¹⁴⁸ Department of Physics and Astronomy, University of Sussex, Brighton, United
Kingdom
¹⁴⁹ School of Physics, University of Sydney, Sydney, Australia
¹⁵⁰ Institute of Physics, Academia Sinica, Taipei, Taiwan
¹⁵¹ Department of Physics, Technion: Israel Institute of Technology, Haifa, Israel
¹⁵² Raymond and Beverly Sackler School of Physics and Astronomy, Tel Aviv University,
Tel Aviv, Israel
¹⁵³ Department of Physics, Aristotle University of Thessaloniki, Thessaloniki, Greece
¹⁵⁴ International Center for Elementary Particle Physics and Department of Physics, The
University of Tokyo, Tokyo, Japan
¹⁵⁵ Graduate School of Science and Technology, Tokyo Metropolitan University, Tokyo,
Japan
¹⁵⁶ Department of Physics, Tokyo Institute of Technology, Tokyo, Japan
¹⁵⁷ Department of Physics, University of Toronto, Toronto ON, Canada
¹⁵⁸ ^(a)TRIUMF, Vancouver BC; ^(b)Department of Physics and Astronomy, York
University, Toronto ON, Canada
¹⁵⁹ Institute of Pure and Applied Sciences, University of Tsukuba, 1-1-1 Tennodai,
Tsukuba, Ibaraki 305-8571, Japan
¹⁶⁰ Science and Technology Center, Tufts University, Medford MA, United States of
America
¹⁶¹ Centro de Investigaciones, Universidad Antonio Narino, Bogota, Colombia
¹⁶² Department of Physics and Astronomy, University of California Irvine, Irvine CA,
United States of America
¹⁶³ ^(a)INFN Gruppo Collegato di Udine; ^(b)ICTP, Trieste; ^(c)Dipartimento di Chimica,
Fisica e Ambiente, Università di Udine, Udine, Italy
¹⁶⁴ Department of Physics, University of Illinois, Urbana IL, United States of America
¹⁶⁵ Department of Physics and Astronomy, University of Uppsala, Uppsala, Sweden
¹⁶⁶ Instituto de Física Corpuscular (IFIC) and Departamento de Física Atómica,
Molecular y Nuclear and Departamento de Ingeniería Electrónica and Instituto de

Microelectrónica de Barcelona (IMB-CNM), University of Valencia and CSIC, Valencia, Spain

¹⁶⁷ Department of Physics, University of British Columbia, Vancouver BC, Canada

¹⁶⁸ Department of Physics and Astronomy, University of Victoria, Victoria BC, Canada

¹⁶⁹ Department of Physics, University of Warwick, Coventry, United Kingdom

¹⁷⁰ Waseda University, Tokyo, Japan

¹⁷¹ Department of Particle Physics, The Weizmann Institute of Science, Rehovot, Israel

¹⁷² Department of Physics, University of Wisconsin, Madison WI, United States of America

¹⁷³ Fakultät für Physik und Astronomie, Julius-Maximilians-Universität, Würzburg, Germany

¹⁷⁴ Fachbereich C Physik, Bergische Universität Wuppertal, Wuppertal, Germany

¹⁷⁵ Department of Physics, Yale University, New Haven CT, United States of America

¹⁷⁶ Yerevan Physics Institute, Yerevan, Armenia

¹⁷⁷ Domaine scientifique de la Doua, Centre de Calcul CNRS/IN2P3, Villeurbanne Cedex, France

^a Also at Laboratorio de Instrumentacao e Fisica Experimental de Particulas - LIP, Lisboa, Portugal

^b Also at Faculdade de Ciencias and CFNUL, Universidade de Lisboa, Lisboa, Portugal

^c Also at Particle Physics Department, Rutherford Appleton Laboratory, Didcot, United Kingdom

^d Also at TRIUMF, Vancouver BC, Canada

^e Also at Department of Physics, California State University, Fresno CA, United States of America

^f Also at Novosibirsk State University, Novosibirsk, Russia

^g Also at Fermilab, Batavia IL, United States of America

^h Also at Department of Physics, University of Coimbra, Coimbra, Portugal

ⁱ Also at Department of Physics, UASLP, San Luis Potosi, Mexico

^j Also at Università di Napoli Parthenope, Napoli, Italy

^k Also at Institute of Particle Physics (IPP), Canada

^l Also at Department of Physics, Middle East Technical University, Ankara, Turkey

^m Also at Louisiana Tech University, Ruston LA, United States of America

ⁿ Also at Dep Fisica and CEFITEC of Faculdade de Ciencias e Tecnologia, Universidade Nova de Lisboa, Caparica, Portugal

^o Also at Department of Physics and Astronomy, University College London, London, United Kingdom

^p Also at Group of Particle Physics, University of Montreal, Montreal QC, Canada

^q Also at Department of Physics, University of Cape Town, Cape Town, South Africa

^r Also at Institute of Physics, Azerbaijan Academy of Sciences, Baku, Azerbaijan

^s Also at Institut für Experimentalphysik, Universität Hamburg, Hamburg, Germany

^t Also at Manhattan College, New York NY, United States of America

^u Also at School of Physics, Shandong University, Shandong, China

^v Also at CPPM, Aix-Marseille Université and CNRS/IN2P3, Marseille, France

- ^w Also at School of Physics and Engineering, Sun Yat-sen University, Guanzhou, China
^x Also at Academia Sinica Grid Computing, Institute of Physics, Academia Sinica, Taipei, Taiwan
^y Also at Dipartimento di Fisica, Università La Sapienza, Roma, Italy
^z Also at DSM/IRFU (Institut de Recherches sur les Lois Fondamentales de l'Univers), CEA Saclay (Commissariat à l'Energie Atomique), Gif-sur-Yvette, France
^{aa} Also at Section de Physique, Université de Genève, Geneva, Switzerland
^{ab} Also at Departamento de Fisica, Universidade de Minho, Braga, Portugal
^{ac} Also at Department of Physics and Astronomy, University of South Carolina, Columbia SC, United States of America
^{ad} Also at Institute for Particle and Nuclear Physics, Wigner Research Centre for Physics, Budapest, Hungary
^{ae} Also at California Institute of Technology, Pasadena CA, United States of America
^{af} Also at Institute of Physics, Jagiellonian University, Krakow, Poland
^{ag} Also at LAL, Université Paris-Sud and CNRS/IN2P3, Orsay, France
^{ah} Also at Nevis Laboratory, Columbia University, Irvington NY, United States of America
^{ai} Also at Department of Physics and Astronomy, University of Sheffield, Sheffield, United Kingdom
^{aj} Also at Department of Physics, Oxford University, Oxford, United Kingdom
^{ak} Also at Institute of Physics, Academia Sinica, Taipei, Taiwan
^{al} Also at Department of Physics, The University of Michigan, Ann Arbor MI, United States of America
^{am} Also at Discipline of Physics, University of KwaZulu-Natal, Durban, South Africa
